Getting Started

The HP 82242A Infrared Printer Module, when installed in your HP-41C, CV, or CX, enables your calculator to communicate via an infrared beam with an HP 82240A Thermal Printer. With this easy-to-use system, you can print text, generate plots and graphics, and run programs that access your printer, without the bother of cable interconnections between devices.

The Printing System

We will make reference throughout this manual to the "printing system". The "printing system" consists of your calculator, an Infrared Printer Module installed in a calculator port, and the HP 82240A Thermal Printer.

Installing Your Module

CAUTION

Be sure the calculator is turned off before connecting or disconnecting the module. Failure to do so may damage the calculator or module, or may disrupt system operation.

8 Getting Started

Your Infrared Printer Module plugs into any of your calculator's ports. With the arrow on the module facing up, push the module into a port until it snaps into place.

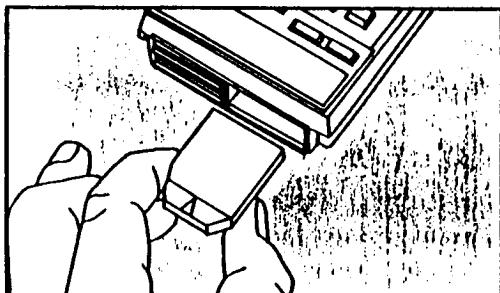

Figure 1-1. Installing the Module

Note:

- If HIP 82106A Memory Modules and the Infrared Printer Module are installed in calculator ports, the memory modules will operate correctly only if installed in the lowest-numbered ports.
- If an HIP 82160A HP-IL Module is installed in a port, the Infrared Printer Module will operate correctly only if the HP-IL Module's PRINT FUNCTION switch is set to DISABLE.
- The Infrared Printer Module will not operate correctly if an HP 82143A Thermal Printer is plugged into the calculator.

When you install the Infrared Printer Module and turn your calculator on, there is an approximately 1.5 second delay before the calculator display lights up.

Your calculator and printer must be positioned within the limits described by figures 1-2 and 1-3 to ensure proper communication:

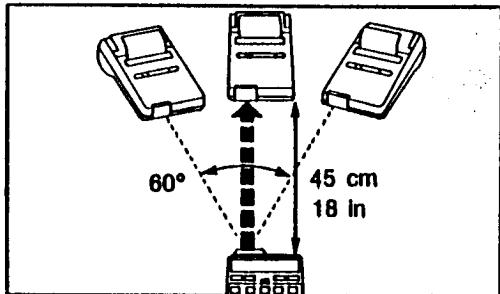

Figure 1-2. Maximum Horizontal Transmitting Distance and Transmitting Angle

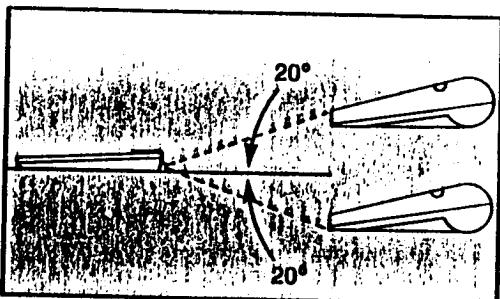

Figure 1-3. Maximum Vertical Transmitting Angle

Note: The maximum transmitting angles are reduced if any of the following are also installed in a calculator port:

- The HP 82160A HP-IL Module.
- The HP 82153A Wand.
- The HP 82104A Card Reader.

Disconnecting Your Module

To remove the module, first turn off the calculator. Then pull the module out of the port and insert a port cover over the empty port.

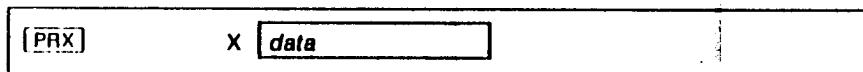

Using This Manual

Chapters 2 through 7 of this manual describe the printing, graphics, plotting, and programming operations available to you with the Infrared Printer Module and HP 82240A Thermal Printer. The manual uses single, colored keys to represent functions not on the calculator keyboard, such as **[ACCOL]**. When you want to execute such a function, you can do it in two ways:

- by using **[XEQ] [ALPHA] function name [ALPHA]**.
- by assigning the function to a key using **[ASN]** and pressing that key in USER mode.

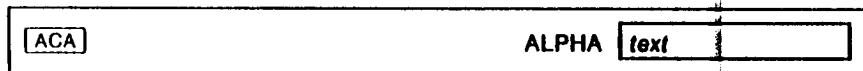

For more information on function execution, refer to the owner's manual for your calculator.

In this manual the description of each function is preceded by a visual guide that summarizes how to execute the function. For example:

The above guide indicates that you must enter data (a number) in the X-register of your calculator to execute the [PRX] function from the calculator keyboard or in a program.

Here's another example:

This guide indicates that you must enter text in the ALPHA register of your calculator to execute the [ACA] function from the keyboard or in a program.

If at any time an error message is displayed by the calculator, refer to the error message appendix for an explanation of its cause. In certain conditions, there may be a short delay before the calculator displays the message.

You may have experience using your calculator with an HP 82143A Thermal Printer, or with an HP 82160A HP-IL Module and HP 82162A Thermal Printer. Many of the print functions built into these two printing systems are similar to or identical to those available to you in your new infrared printing system. Some new functions have been added to your infrared system, and a few functions from the earlier systems have not been incorporated. You may choose to review briefly or skip entirely chapters 2 through 7 of this manual and refer directly to appendix E, "If You've Used an HP Thermal Printer...." Appendix E summarizes the module function set, highlights differences from the earlier printing systems, and in some cases refers you back to the main body of the manual for detailed explanations.

Controlling Printer Operations

In following chapters, you'll learn how to print text, generate graphics and plots, and print information from calculator programs. First, though, you'll find it helpful to understand how the set of calculator flags and module functions described in this chapter affect printer operations. These flags and functions enable you to control *how* and *when* printer operations are executed.

Calculator Flags That Control Printer Operations

The calculator flags that influence printer operations are user flags; you can set, clear, and test them.

The Printer Enable Flag

The Printer Enable Flag (flag 21) is used to control printing in *programs* that contain specific print functions. Flag 21 has no effect on print functions executed from the keyboard. When flag 21 is set, printing functions contained in a program are executed normally. When flag 21 is clear, execution of printing functions in a program is suppressed.

The Double-Wide Flag

The Double-Wide Flag (flag 12) is a special-purpose user flag that controls how characters are printed on the printer paper. When flag 12 is set, all characters and graphics columns are printed double-wide.

The Lowercase Flag

The Lowercase Flag (flag 13) is a special-purpose user flag that controls the way letters A through Z are printed. When flag 13 is set, letters A through Z, including those in program listings, are printed in lowercase form. (Other characters are not affected by flag 13.)

Table 2-1. The Printer Enable, Double-Wide, and Lowercase Flags.

Flag	Set	Clear
Flag 21 (Printer Enable)	Printer operations are performed normally.	In programs, printer operations are ignored.
Flag 12 (Double-Wide)	Characters are accumulated and printed double-wide.	Characters are accumulated and printed single-wide.
Flag 13 (Lowercase)	Letters A—Z are accumulated and printed in lowercase.	Letters are accumulated and printed without change of case.

The Print Mode Flags

The Print Mode Flags (flags 15 and 16) determine the print mode of the system:

Table 2-2. The Print Mode Flags.

Flag 15	Flag 16	Print Mode
clear	clear	MAN (manual)
clear	set	NORM (normal)
set	clear (or set)	TRACE

- In **MAN (manual)** mode, the printer is idle and does not print unless a print function is executed by you or a program. In **MAN** mode, program listings are printed left-justified.
- In **NORM (normal)** mode, the printer prints numbers and **ALPHA** strings that are keyed in, function names as they are executed from the keyboard, and output from print functions. In programs, only output from print functions and the **[PROMPT]** function are printed. In **NORM** mode, program listings are printed left-justified.
- In **TRACE** mode, the printer prints numbers and **ALPHA** strings that are keyed in, function names, intermediate and final answers, and output from print functions. In **TRACE** mode, program listings are printed in a special "packed" or condensed form.

Note that your calculator clears all special-purpose user flags (flags 11-20) each time you turn it on. However, once you set any of the printer flags, the printer will operate accordingly until you clear the flag or turn the calculator off. Notice that the conditions of the flags do not affect the calculator's display.

Functions That Control Printer Operations

You can control additional printer operations by executing the following functions.

Turning Print Functions On and Off

PRTON

When you execute the **PRTON** (*print on*) function, the output mode of your printing system is set to PRTON. In this mode, printing operations are executed normally.*

When you install the Infrared Printer Module and turn your calculator on, the printing system is *automatically* set to PRTON mode. The printing system will remain in PRTON mode until you execute the **PRTOFF** function (described next).

(When you execute **PRTON**, flag 21 is automatically set. If you clear flag 21 in PRTON mode, execution of print functions in programs is suppressed and print functions executed from the keyboard are performed normally.)

PRTOFF

When you execute the **PRTOFF** (*print off*) function, the output mode of the printing system is set to PRTOFF. In this mode, all printing operations (those executed in programs and those executed from the keyboard) are suppressed.

* **PRTON** sets flag 55 (the Printer Existence Flag). **PRTOFF** clears flag 55. Flag 55 is not a user flag; it cannot be directly set or cleared. It *can* be tested.

If you have executed [**PRTOFF**], the printing system remains in PRTOFF mode until you do one of the following:

- Execute the [**PRTON**] function.
- Execute the [**RESETP**] function (described at the end of this chapter).
- Turn the calculator off, remove the Infrared Printer Module, reinsert the module, and turn the calculator on again.

Setting the Print Mode

In addition to directly setting the states of flags 15 and 16, you can specify the print mode of your printer by executing the following three functions.

[**MAN**]

When you execute the [**MAN**] (*manual*) function, the print mode of your printer is set to MAN.

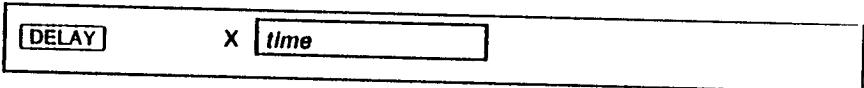

[**NORM**]

When you execute the [**NORM**] (*normal*) function, the print mode of your printer is set to NORM.

[**TRACE**]

When you execute the [**TRACE**] function, the print mode of your printer is set to TRACE.

Setting the Delay

The **DELAY** function enables you to specify how long your calculator waits between sending lines of information to the HP 82240A Thermal Printer. The number in the X-register is the delay time, in seconds. When you install the Infrared Printer Module and turn your calculator on, the delay is set to 1.8 seconds. The maximum delay is 1.9 seconds. (The actual delay will be the number in the X-register, plus or minus one tenth of a second.)

DELAY can be useful when your calculator is sending multiple lines of information to the printer (for example, in execution of the **CAT** function described in chapter 3). To optimize the efficiency of the printing operation, set the delay just longer than the time the printhead in your printer requires to print one line of information. (The printhead speed varies from printer to printer). Be aware that if you set the delay *shorter* than the time to print one line, you may lose information. Also, as the battery in your printer loses charge, the printhead slows down, and, if you have previously decreased the delay, you may have to increase it to avoid losing information. (Battery discharge will *not* cause the printhead to slow to more than the 1.8 second default delay setting.)

Resetting the System Control Flags and Functions

RESETP

When you execute the **RESETP** function, the flags and functions discussed in this chapter are returned to their default state:

- Flag 12 clear (characters accumulated and printed single-wide).
- Flag 13 clear (characters accumulated and printed without change of case).
- Output mode set to PRTON.
- Print mode set to MAN (flags 15 and 16 clear).
- Delay set to 1.8 seconds.

(**RESETP** returns another set of functions, described in chapter 4, to their default state. Refer to "Printing the Contents of the Print Buffer" in chapter 4.)

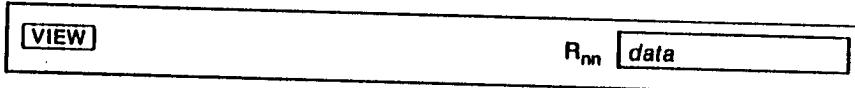

Standard Printing Operations

Information stored in your calculator may be printed directly using the functions described below. These functions are grouped into four categories in this chapter:

- Calculator functions; when executed, the outcome returned to the display is printed.
- Print-register functions; when executed, the contents of calculator registers are printed.
- Print-program functions; when executed, programs or parts of programs stored in your calculator are printed.
- Print-key assignments and print-status functions; when executed, calculator key assignments and flag status are printed.

Calculator Functions That Print

There are five standard calculator functions that will, in addition to performing their normal functions (described in the owner's manual for your calculator), automatically generate printed output. These functions are **VIEW**, **AVIEW**, **PROMPT**, **ADV**, and **CATALOG**.

When you execute the **[VIEW]** (*view register contents*) function, the contents of the specified register are printed, as well as displayed by the calculator. The printing system can be set to **MAN**, **NORM**, or **TRACE** mode.

[AVIEW]

ALPHA

text

When you execute the [AVIEW] (*ALPHA view*) function, the contents of the ALPHA register are printed, as well as displayed by the calculator. The printing system can be set to MAN, NORM, or TRACE mode.

[PROMPT]

ALPHA

prompt

If the printing system is set to NORM or TRACE mode and you execute the [PROMPT] function, the contents of the ALPHA register (the prompt) are printed, as well as displayed by the calculator.

[ADV]

When you execute the [ADV] (*advance*) function, either in a program or from the keyboard, any information held in the print buffer is printed on the current line, and the printer paper is advanced a single line. (For an explanation of the print buffer, refer to "The Print Buffer" in chapter 4.) If the printing system is not operating, your calculator ignores the [ADV] command.

Your HP 82240A Thermal Printer has an ADVANCE switch. When you activate the switch, the paper will advance one line, but information held in the print buffer will not be printed.

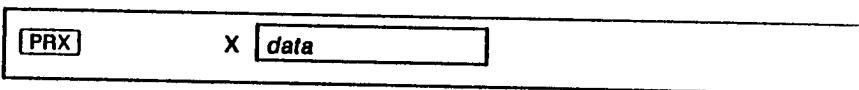

[CAT] *n*

When you execute the [CAT] (*catalog*) function, your calculator displays the contents of any of the calculator catalogs.* When the printing system is set to TRACE mode, the contents of the specified catalog are also printed. When you execute [CAT] 1, the number of bytes that each program occupies in program memory is printed next to the end of each program. (Refer to the owner's manual for your calculator for a discussion of bytes.)

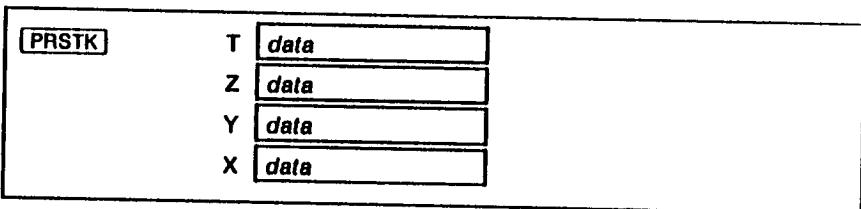

* You may wish to use the [DELAY] function (discussed in chapter 2) to improve the print speed performance during execution of [CAT]. [DELAY] will also improve the print speed performance during execution of the following functions (discussed later in this chapter): [RUN(G)], [RUN(GX)], [RUN], [RUNS], and [PROGAGS].

Printing Registers

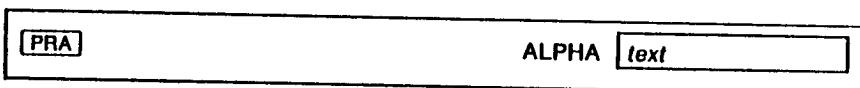

Six functions enable you to print the contents of certain registers in the calculator. Any listing can be stopped by pressing **R/S**.

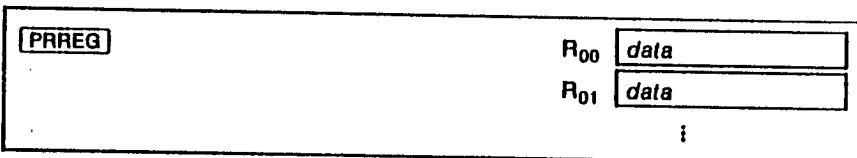

When you execute the **PRX** (*print X*) function, the contents of the X-register are printed and marked with ***.

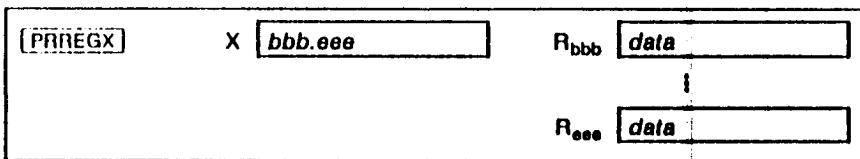

When you execute the **PRSTK** (*print stack*) function, the contents of the automatic memory stack are printed and labeled in T, Z, Y, X order.

When you execute the **PRA** (*print ALPHA*) function, the contents of the ALPHA register are printed. The printed output is left-justified; it lines up with the left margin.

When you execute the **PRREG** (*print registers*) function, the contents of all currently allocated storage registers, beginning with R₀₀, are printed and labeled. When a register contains ALPHA characters, your printer encloses these characters in quotes: R01 = "ABC".

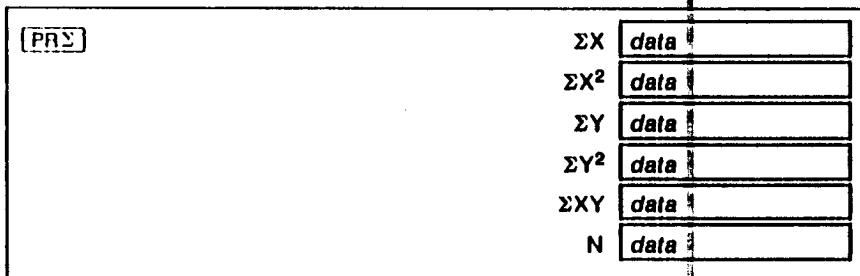

The **[PRREGX]** (*print registers as directed by X*) function provides you with control over which registers you print. **[PRREGX]** uses a number in the X-register to control printing. Before executing **[PRREGX]**, place a control number in the X-register using the following format:

bbb.eee

where *bbb* is the beginning data storage register address, and *eee* is the ending data storage register address. The *bbb* portion can be one to three digits. The first three digits of the *eee* portion define the ending data storage register. For example, specify registers R_{03} through R_{07} by placing 3.007 in the X-register.

Note that if you enter 3.7 in the X-register and execute the **[PRREGX]** function, the contents of registers R_{03} through R_{319} (the highest numbered data storage register) are printed! Similarly, if you enter 3.07 in the X-register, the contents of registers R_{03} through R_{70} are printed.

The **[PRΣ]** (*print statistics registers*) function enables you to print the contents of the currently defined statistics registers. (Refer to the owner's manual for your calculator for information about **[ΣREG]** and how statistics registers are defined.) When you execute the **[PRΣ]** function, the contents of all six statistics registers are printed.

Example: Printing Registers. In this example, we'll print the contents of five data storage registers, and then print the contents of the ALPHA register in double-wide and lowercase modes.

Allocate 17 storage registers, then clear them and store 2.0000 in R₀₅.

[SIZE] 017

[CLRG]

2 [STO] 05

Specify R₀₁ through R₀₅ and print their contents. (HP 82240A Thermal Printer: MAN mode.)

1.005

[PRREGX]

R₀₁= 0.0000
R₀₂= 0.0000
R₀₃= 0.0000
R₀₄= 0.0000
R₀₅= 2.0000

Now print an ALPHA string double-wide. Clear the Double-Wide Flag afterwards. (HP 82240A Thermal Printer: MAN mode.)

[SF] 12

[ALPHA] STRETCH [ALPHA]

[PRA]

[CF] 12

STRETCH

Print an ALPHA string in lowercase. Clear the Lowercase Flag afterwards. (HP 82240A Thermal Printer: MAN mode.)

[SF] 13

[ALPHA] SQUEEZE [ALPHA]

[PRA]

[CF] 13

squeeze

Printing Programs

When you execute the **[PRP]** or **[LIST]** functions, programs or parts of programs that you have stored in program memory are printed. The print mode determines the format in which program lines are printed. You can stop the printing operation at any time by pressing **[R/S]**. These two functions are not programmable.

PRP

When you execute the **PRP** (*print program*) function, a specific program stored in program memory is printed. The calculator prompts you for the name of the program you wish to print. Simply key in the name of the program (by pressing **ALPHA** name **ALPHA**); printing will begin at the first line of the specified program. If you do not specify a program name in response to the prompt (if you press **ALPHA ALPHA**), the printer will print the program to which the calculator is currently positioned, beginning at the first line. (If you are using an HP 41CX calculator, or an HP 41C or CV calculator with an HP 82182A Time Module installed in a calculator port, the time and date will also be printed at the head of the program listing.)

LIST *nnn*

When you execute the **LIST** function, a specified number of program lines are printed. First, position the calculator to the desired program and then to the line within the program where you wish printing to begin. Then execute **LIST**. When prompted, key in a three-digit number specifying the number of lines you wish to print.

Example: Printing a Program. The following program listings show the two format options specified by the print mode. (For program listings, the format in NORM mode is identical to that in MAN mode, except that, in NORM mode, the **PRP** instruction is printed.) The program name is SAMPLE. To execute the example, first key in the program, using the listing shown in the example.

Print the program named SAMPLE.

PRP

ALPHA SAMPLE ALPHA

Printing Status and Key Assignments

If you wish to review the calculator's internal conditions, you can use the **[PRKEYS]** and **[PRFLAGS]** functions to print this information at any time.

[PRKEYS]

When you execute the **[PRKEYS]** (*print key assignments*) function, in a program or from the keyboard, the keycode of each reassigned key, followed by the name of the function or program assigned to each key, is printed. A keycode is row-column code of a key's location on the keyboard. Your printer prefixes the keycodes for shifted key locations with a — (minus sign).

[PRFLAGS]

When you execute the **[PRFLAGS]** (*print flags*) function, from the keyboard or in a program, the following information is printed:

- Number of data storage registers (SIZE = *nnn*).
- Location of first statistics register (Σ = *nnn*).
- Trigonometric mode (DEG, RAD, or GRAD).
- Display format (FIX *n*, SCI *n*, or ENG *n*).
- Status of all flags (F *nn* SET, or F *nn* CLEAR).

Example: Printing Calculator Information.

Print the status of the calculator flags and other information. (HP 82240A Thermal Printer: MAN mode.)

PRFLAGS

STATUS:
SIZE = 017
X = 11
DEC
FIX 4

FLAGS:

FF 00	CLEAR

FF 4B	CLEAR
FF 4C	CLEAR
FF 4D	CLEAR
FF 4E	SET

Accumulating Printer Output

The functions described in this chapter (and the following chapter on graphics) enable you to build up, or *accumulate*, a string of information in your printer, and then print the string. You can combine numeric, ALPHA, and graphics information in the same string. In this chapter, you'll learn how to:

- Accumulate alpha-numeric data from the registers of your calculator, and numeric codes for a host of characters not available on your calculator keyboard.
- Accumulate spacing and underlining commands.
- Print your accumulated strings of information.

Your printing system must be set to MAN mode to properly execute these operations. In NORM or TRACE mode, accumulated information will be printed prematurely.

The Print Buffer

In the previous chapter, "Standard Printing Operations," you learned a number of functions that you can execute to directly print information contained in your calculator. When you execute these functions, the information to be printed actually makes a short stop in the HP 82240A Thermal Printer in a special set of registers called the *print buffer*. The information automatically enters, then leaves the buffer en route to its final destination on the printer paper.

In the following sections, you'll learn how to use the print buffer as a temporary *storage* location for information to be printed. The print buffer is made up of 200 storage locations called bytes. Most types of information, such as alpha-numeric characters, occupy one byte in the buffer. Other types of information, such as mode change commands (for exam-

ple, the "start underlining function" discussed later in this chapter), and graphics instructions and custom characters (discussed in the next chapter), occupy more than one byte in the buffer. Appendix C presents a complete listing of character types and commands and the space they occupy in the buffer.

Accumulating Characters

When the following three functions are executed, alpha-numeric characters are accumulated in the print buffer.

When you execute the **ACA** (*accumulate ALPHA*) function, all of the characters from the **ALPHA** register are copied and placed in the print buffer at the end of any string of characters already in the buffer. **ACA** can be executed from the keyboard or in a running program.

Example: Accumulating Characters. In this example, we'll first build an **ALPHA** string in the print buffer using the **ACA** command, and then print the string.

Advance the paper (and print whatever is already in the print buffer). Place the letters **AB** in the **ALPHA** register and accumulate them in the print buffer without printing.

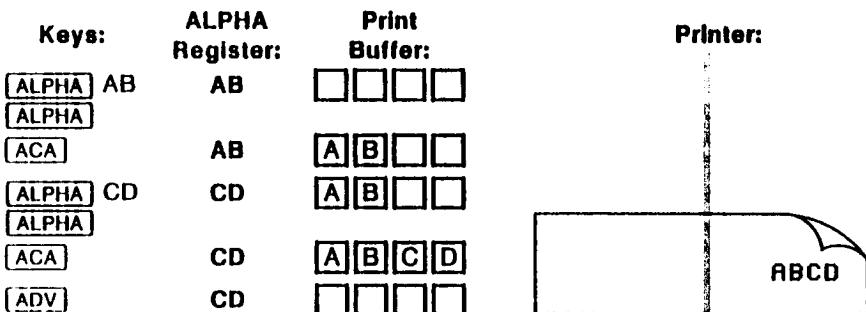

ADV
ALPHA AB ALPHA
ACA

Now accumulate the letters **CD** in the buffer, print the entire string and advance the paper. (HP 82240A Thermal Printer: MAN mode.)

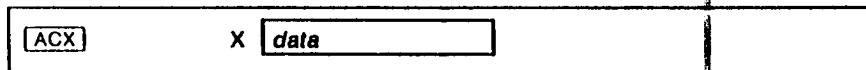

ALPHA CD ALPHA
ACA
ADV

Here is what happened when you accumulated the ALPHA characters using [ACA] and then executed [ADV].

Remember that the status of flags 12 and 13 also affects how characters are accumulated in the print buffer. If you set flag 12, characters are accumulated double-wide. If you set flag 13, letters A through Z are accumulated in lowercase.

The [ACX] (accumulate X-register) function operates in the same way as [ACA], except that when you execute [ACX], information from the X-register is accumulated in the print buffer.

[ACX] accumulates the entire formatted number into the print buffer—the number (according to the current display format) and the space for the sign of the number (blank for a positive number, filled with a minus sign for a negative number). If you wish to omit the initial space for positive numbers, use [ARCL] and [ACA] to accumulate numbers. You can do this by pressing [ARCL] ⌘ X in ALPHA mode, which recalls the contents of the X-register into the ALPHA register, and then using [ACA] to accumulate those ALPHA characters. When you execute [ARCL], a minus sign will be copied, but not a leading blank for a positive number.

ACCHRX **character code**

When you execute the **ACCHR** (*accumulate character*) function, one standard printer character is accumulated in the print buffer. The number in the X-register specifies the particular character to be accumulated.

ACCHR enables you to accumulate and print many more characters than are available on the keyboard. Appendix D lists the standard characters and their numeric codes for the HP 82240A Thermal Printer. Note that the table includes two characters sets; one when the printing system is in MAPON mode, the other when the printing system is in MAPOFF mode.

MAPON

When you execute the **MAPON** (*character remapping on*) function, the character set mode of the printing system is set to MAPON. Characters 0-31 and 123-127 are *remapped* so that (with the exceptions noted in appendix D) the character set matches that of the HP 82162A Thermal Printer and HP 82143A Thermal Printer. You'll find the **MAPON** function very useful (and in some cases, necessary) if you wish to run programs that have been written for these two printers and utilize their extended character set. (Appendix D contains detailed information on this topic.)

When you install the Infrared Printer Module and turn your calculator on, the printing system is automatically set to MAPON mode. The printing system remains in MAPON mode until you execute the **MAPOFF** function (described next).

MAPOFF

.

When you execute the **MAPOFF** (*character remapping off*) function, the character set mode of the printing system is set to MAPOFF; character remapping is turned off. You'll note that the character set in MAPOFF mode matches that listed on pages 18-19 of the owner's manual for your HP 82240A Thermal Printer. Also note that in MAPOFF mode, characters 4, 10, and 27 are *control* characters. Refer to appendix D for an explanation of control characters.

If you have executed [MAPOFF], the printing system remains in MAPOFF mode until you do one of the following:

- Execute the [MAPON] function.
- Execute the [RESETP] function.
- Turn your calculator off, remove the Infrared Printer Module, reinsert the module, and turn your calculator on.

Example: Accumulating Characters, Single- and Double-Wide.

Wide. In this example, we accumulate a character that is specified by a character code, and print that character double-wide.

First, print whatever is in buffer. Then set the printing system to MAPON mode and set the Double-Wide Flag. Enter the character code for 'a' in the X-register and accumulate it. Next, clear the Double-Wide Flag.

```
ADV
MAPON
■ SF 12
4
ACCHR
■ CF 12
```

Enter the number -2.6 in the X-register. Enter an ALPHA string and append the X-register to it. After accumulating this ALPHA string, print the contents of the buffer and advance the paper. (HP 82240A Thermal Printer: MAN mode.)

```
2.6 CHS
ALPHA
SPACE = SPACE
■ ARCL □ X
ALPHA
ACA
ADV
```

Accumulating Spaces

[SKPCHR]	X	number	
----------	---	--------	--

When you execute the [SKPCHR] (skip character) function, character spaces are accumulated in the print buffer (character positions are skipped). The number placed in the X-register specifies the number of spaces to skip. This function allows you to format information you accumulate and print, without entering individual spaces. You can skip up to 24 spaces. (Your HP 82240A Thermal Printer has a 24 character line; skipping 24 spaces is the same as executing a paper advance.)

Accumulating Underline

STARTU

When you execute the **STARTU** (*start underlining*) function, the underlining mode of the printing system is set to STARTU. An instruction to underline all subsequently printed characters is accumulated in the print buffer. The printing system remains in STARTU mode until you do one of the following:

- Execute the **STOPU** function (described next).
- Execute the **RESETP** function.
- Turn the *printer* off, then on.

STOPU

When you execute the **STOPU** (*stop underlining*) function, the printing system is set to STOPU mode. An instruction to resume printing of all characters without underlining is accumulated in the print buffer. The printing system remains in STOPU mode until you execute the **STARTU** function. When you turn your printer on, the printing system is automatically set to STOPU mode.

Example: Accumulating Characters With and Without Underlining. This example shows how to accumulate characters with and without underlining in the same ALPHA string.

Print whatever is in the buffer, advance the paper, and accumulate the STARTU command.

ADV

STARTU

Enter an ALPHA string and accumulate it.

ALPHA E **SPACE** **ALPHA**

ACA

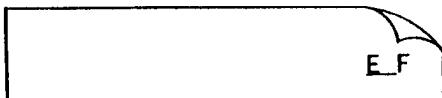

Now accumulate the STOPU command. Enter a new ALPHA string and accumulate it. Print the contents of the buffer and advance paper.
(HP 82240A Thermal Printer: MAN mode.)

STOPU

ALPHA F **ALPHA**

ACA

ADV

E_F

Here is what happened when you accumulated **[STARTU]** and **[STOPU]** escape sequences in your print buffer while accumulating a string of text. (We'll represent the **STARTU** command by **!!**, the **STOPU** command by **\$\$**.)

Keys:	ALPHA Register:	Print Buffer:	Printer:
[STARTU]		!!	
[ALPHA E]	E	!!E	
[SPACE]	E	!!E	
[ALPHA]	E	!!E	
[ACA]	E	!!E	
[STOPU]	E	!!E\$\$	
[ALPHA F]	F	!!E\$\$	
[ALPHA]	F	!!E\$\$	
[ACA]	F	!!E\$\$F	
[ADV]	F	!!E\$\$F	E_F

Printing the Contents of the Print Buffer

After you have accumulated the desired characters in the print buffer, you can instruct the printer to print the contents of the buffer. The contents of the buffer are printed left to right—the first character placed in the buffer is printed at the left, and the last character is printed at the right. The buffer clears as its contents are printed.

[ADV]

When you execute the **[ADV]** (*advance*) function, the contents of the print buffer are normally printed right-justified; lined up with the right margin of the paper. If the information in the buffer exceeds 27 bytes, the information is printed *left-justified*.

PRBUF

When you execute the **PRBUF** (*print buffer*) function, the contents of the print buffer are printed left-justified.

In addition, the information in the print buffer is printed when:

- in MAN, NORM, or TRACE mode, you execute any of the functions described in the previous chapter, "Standard Printing Operations."
- in NORM or TRACE mode, you execute any function whose name is printed when you execute the function in these two modes.

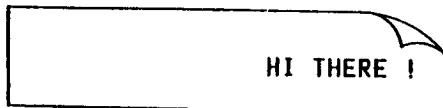

FMT

When you execute the **FMT** (*format*) function, the formatting done by **ADV** and **PRBUF** is superceded. If **FMT** is executed before or after accumulating a string of information in the buffer, the string is centered on the printer paper. Centered lines are centered to the nearest dot position in the printed output. If **FMT** is executed between accumulated strings of information, the strings are separated (and left- and right-justified). **FMT** will not format any string that **ADV** left-justifies.

Example: Printing the Contents of the Print Buffer Using the **ADV, **PRBUF**, and **FMT** Functions.** In this example, we'll print the same ALPHA string in four different formats.

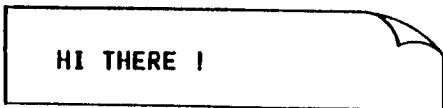

Accumulate the ALPHA string HI THERE and then accumulate character 33, 'I'. Print the complete string right-justified. (HP 82240A Thermal Printer: MAN mode.)

ALPHA HI **SPACE** THERE
SPACE **ALPHA**
ACA
33 **ACCHR**
ADV

Print the same string left-justified. If you have not changed the contents of the ALPHA or X-registers, you can simply execute the accumulate functions again. (HP 82240A Thermal Printer: MAN mode.)

ACA
ACCHR
PRBUF

Now print the string centered using the [FMT] function. (HP 82240A Thermal Printer: MAN mode.)

[FMT]
[ACA]
[ACCHR]
[ADV]

Print the ALPHA string separated from character 33 by executing the [FMT] function between accumulation of the ALPHA string and character 33. (HP 82240A Thermal Printer: MAN mode.)

[ACA]
[FMT]
[ACCHR]
[ADV]

When the print buffer is filled, the printer automatically prints one line of information to provide additional space. However, *some information may be lost* when this operation is performed. If information is lost by overflowing the buffer, the "Z" character is printed. In such a case, your printer may require a linefeed command ([ADV] or [PRBUFE]) to resume printing.

[RESETP]

When you execute the [RESETP] function, the printer modes described in this chapter are returned to their default state:

- Character set mode set to MAPON.
- Underline mode set to STOPU.

Note that when you execute [RESETP], any information in the print buffer is printed and the buffer is cleared. (Accumulated information is first grouped into 26- to 28-byte packages in the Infrared Printer Module before being sent to the printer. When you execute [RESETP], any accumulated information in the module is lost.)

(Remember that [RESETP] also returns the system control flags and functions to their default state, as described in "Resetting the System Control Flags and Functions" in chapter 2.)

Graphics

Special graphics functions described in this chapter afford you precise control over the smallest component of printed information, the individual dot. Using these functions, you can build and print your own special characters and non-character graphics. In this chapter, we'll show you how to:

- Specify a column of dots using graphics functions.
- Accumulate columns.
- Skip columns.
- Build, accumulate, store, and print your own custom characters.
- Build a graphics pattern using a "specified length graphics sequence".

Your printing system must be set to **MAN** mode to properly execute these operations. In **NORM** or **TRACE** mode, the contents of the print buffer will be printed prematurely.

The Character Matrix

All standard characters are defined by dots in a five-by-seven character matrix. To provide spaces between standard characters, two empty columns and an empty row are added to form a seven-by-eight full matrix.

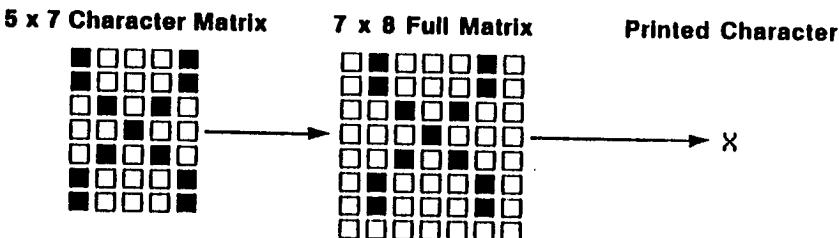

Figure 5-1. The Character Matrix.

Using graphics functions, you can actually tell your HP 82240A Thermal Printer which dots to print in each of the 166 columns of a printed line (including the one row and two columns left blank with standard characters).

Specifying a Column of Dots

You'll use a *column print number* to specify which dots to print in a particular column. Each dot in the column is assigned a numeric value, as shown in the following illustration. To calculate the column print number, simply add the numbers for the dots you want to print in the column; the sum is the column print number. The column print number can be 0 through 255.

Value	Dots to Print	Print Entry
1	 →	1
2	 →	2
4	 →	
8	 →	
16	 →	
32	 →	32
64	 →	64
128	 →	
		<u>99</u> ← Column Print Number
Value	Dots to Print	Print Entry
1	 →	1
2	 →	2
4	 →	4
8	 →	8
16	 →	16
32	 →	32
64	 →	64
128	 →	128
		<u>255</u> ← Column Print Number

Figure 5-2. Calculating the Column Print Number.

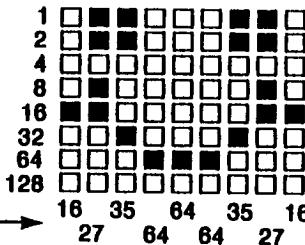

Accumulating Columns

ACCOL

X **c-p number**

When you execute the **ACCOL** (accumulate column) function, a single dot-column is accumulated in the print buffer. The specific dot pattern is determined by the column print number in the X-register.

Example: Building and Printing a Graphics Pattern. The following example shows how to accumulate and print the nine-column pattern shown below.

Column Print Numbers → 16 35 64 35 16
27 64 64 27

First clear the print buffer and advance the paper. Then enter and accumulate the ALPHA string A FINE DAY.

ADV

ALPHA A **SPACE** FINE **SPACE**

DAY **SPACE** **ALPHA**

ACA

Now accumulate the first four column print numbers for the dot pattern.

16 **ACCOL**

27 **ACCOL**

35 **ACCOL**

64 **ACCOL**

Accumulate column print number 64 two more times.

ACCOL

ACCOL

Accumulate the last three column print numbers and print the contents of the buffer. (HP 82240A Thermal Printer: MAN mode.)

35 **ACCOL**

27 **ACCOL**

16 **ACCOL**

PRBUF

A FINE DAY □

Skipping Columns

SKPCOL	X	number
---------------	---	---------------

When you execute the **SKPCOL** (*skip column*) function, a specified number of blank columns is accumulated in the print buffer. The number in the X-register indicates the number of columns to skip. You can skip from 0 up to 166 columns using **SKPCOL**. (Your HP 82240A Thermal Printer has a 166 column line; skipping 166 columns is the same as executing a paper advance.)

Building Special Characters

If you want to repetitively print a custom character that is not in the standard character set, you can use the following special-character functions to build, and print a custom character that can be stored and recalled.

BLDSPEC	X	c-p number
	Y	reserved

The **BLDSPEC** (*build special character*) function uses up to seven column print numbers, one at a time, to define the dot pattern for your special character. Be sure to clear the X- and Y-registers of the calculator (press **0** [**ENTER↑**]) before beginning to build your special character.* Execute **BLDSPEC** for each of the column print numbers, left to right. As you execute **BLDSPEC**, a character *representation* is built in the X- and Y-registers and displayed by your calculator. (The display is otherwise meaningless.) The representation can be stored in any register for use at any time. If you specify more than seven print columns, earlier numbers are lost—only the last seven numbers will be used to form the character. If you specify fewer than seven numbers, blank columns will remain in the undefined left part of the character.

* The **BLDSPEC** function will execute correctly if *numeric* data is present in the X- and Y-registers. It will not execute correctly if *alpha* data is present in these registers. You can skip the register-clearing step if numeric data is present in the X- and Y-registers.

Note that your special characters can use columns 1 and 7, which are left blank when standard characters are printed. Unlike [ACCOL]-accumulated graphics, special characters *cannot* use the eighth (underline) dot in each column.

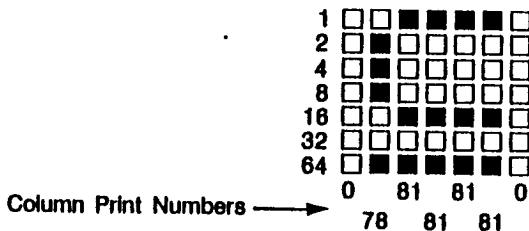

ACSPEC

X *representation*

When you execute the [**ACSPEC**] (*accumulate special character*) function, a special character is accumulated in the print buffer. The X-register must contain the character representation generated by the [**BLDSPEC**] process. (The representation may be recalled into the X-register from a register where it has been previously stored).

Example: Building, Storing, and Printing a Special Character.

Following is an example showing how to build, store and print the special character shown below.

Clear the X- and Y-registers. Then build the special character and store its representation in R₀₁.

0 [**ENTER**]

0 [**BLDSPEC**]

78 [**BLDSPEC**]

81 [**BLDSPEC**]

81 [**BLDSPEC**]

81 [**BLDSPEC**]

81 [**BLDSPEC**]

0 [**BLDSPEC**]

STO 01

Clear the X-register, then enter and accumulate the ALPHA string A__.

⬅

ALPHA A **SPACE** **ALPHA**

ACSA

Now recall and accumulate the special character representation. Then enter and accumulate the ALPIIA string _B and print the contents of the buffer.

```
RCL 01
[ACSPEC]
[ALPIIA] [SPACE] B [ALPHA]
[ACA]
[PRBUF]
```

Justification and Formatting of Graphics

When you use the **[ADV]** function to print graphics strings, your HP 82240A Thermal Printer will *left-justify*:

- Any graphics string greater than 27 total bytes in length. (2 bytes are always accumulated to begin a graphics string.)
- Strings that contain information accumulated with the **[ACCOL]** or **[ACSPEC]** functions, unless the **[ACCOL]**- or **[ACSPEC]**-accumulated information *begins* the string.
- Any **[ACCOL]**- or **[ACSPEC]**-accumulated string that contains a mode-change instruction (**STARTU**, **STOPU**, **SF** 12, or **CF** 12).

The **[FMT]** function will *not* format any graphics string that **[ADV]** left-justifies.

Graphics in MAPOFF Mode

All the graphics functions described in this chapter operate identically in MAPOFF mode. Additionally, in MAPOFF mode, you can use control character 27 to begin a *specified length graphics sequence*. To initiate such a sequence, use **[ACCHR]** to accumulate control character 27. Then use **[ACCLIR]** to accumulate *nnn* (a number from 1 to 166 that specifies the length, in bytes, of the graphics sequence.) (You must calculate the number of bytes in the string before initiating the graphics sequence.)

In a specified length graphics sequence, all data bytes generated by accumulate functions or mode changes are treated as graphics bytes (as column print numbers).*

In a specified length graphics sequence, **[ADV]** left-justifies any graphics sequence greater than 27 total bytes (as in standard graphics operations). However, **[ADV]** right-justifies sequences that are less than 27 total bytes and contain imbedded **[ACCOL]** or **[ACSPEC]** instructions or mode change instructions. **[FMT]** does not format any string that **[ADV]** left-justifies.

* A useful application of a specified length graphics sequence utilizes the **[XTOA]** function (built into the HP-41CX calculator, the HP 82180A Extended Functions/Memory Module, and the HP 82183A Extended I/O Module). **[XTOA]** transfers into the ALPHA register the equivalent ASCII character for any number (character code) entered into the X-register; you can enter up to a 24 character string into the ALPHA register. In a specified length graphics sequence, when you subsequently execute **[ACA]**, each successive character code in the string is treated as a column print number. The string can of course be stored and recalled, since it is in the ALPHA register and thus can be used in the same way as a special character built with **[BLDSPEC]** and accumulated with **[ACSPEC]**. Remember that a special character built with **[BLDSPEC]** may be only seven columns wide and cannot utilize the eighth row of dots in the character matrix, while a graphics pattern built with **[XTOA]** can be 24 columns wide and can utilize the eighth row of dots.

Plotting

Using the five plotting operations described in this chapter, you can plot any valid single-valued mathematical function.

In this chapter, you'll learn how to:

- Use the elements of the standard plotting format.
- Plot with special characters.
- Use an interactive plotting operation called **[PRPLOT]**.
- Use plotting operations in a program.
- Use plotting functions that generate individual parts of a plot.

Your printing system must be in MAN mode to properly execute these plotting operations. In NORM or TRACE mode, the contents of the print buffer will be printed prematurely.

Let's begin this chapter by showing you the capabilities of the plotting operation called **[PRPLOT]**.

Example: Plotting a Function. In this example, we'll plot the function

$$y = \sin x$$

This example assumes that your calculator is in degrees mode and the allocation of data storage registers is **[SIZE] 017**.

First, enter a program that computes the function. (The program name is WIGGLE.)

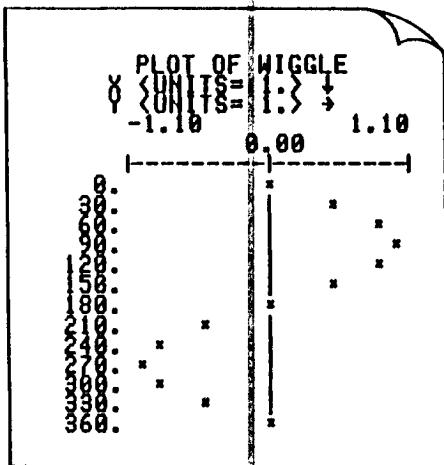

Keys:	Display:	Description:
PRGM		
GTO	• •	
LBL		
ALPHA	WIGGLE	Names the program.
ALPHA	01 LBL ^T WIGGLE	
SIN	02 SIN	Computes $\sin x$ and leaves the result in X .
GTO		Ends program.
PRGM	0.0000	

Next, clear register R₀₃ ([PRPLOT] uses R₀₃.) Then, execute [PRPLOT]; your calculator will prompt you for plotting information. (Plot the function for x from 0° to 360° in steps of 30°. To allow room for y values close to -1 and +1, draw the y axis from -1.1 to +1.1. Draw the x -axis at $y = 0$.)

Keys:	Display:	Description:
0 STO 03	0.0000	Clears register R03.
PRPLOT	NAME?	Begins plotting routine. Displays NAME prompt.
WIGGLE R/S	Y MIN?	Enters program name. Displays Y MIN? prompt.
1.1 CHS R/S	Y MAX?	Enters minimum y value. Displays Y MAX? prompt.
1.1 R/S	AXIS?	Enters maximum y value. Displays AXIS? prompt.
0 R/S	X MIN?	Enters x -axis location. Displays X MIN? prompt.

Keys:	Display:	Description:
0 [R/S]	X MAX?	Enters minimum x value. Displays X MAX? prompt.
360 [R/S]	X INC?	Enters maximum x value. Displays X INC? prompt.
30 [R/S]		Enters x increment value. Begins printing.

IIP 82240A Thermal Printer: MAN mode.

[PRPLOT] automatically supplies each x value, runs your function program (WIGGLE), and plots the calculated point using the y value returned in the X-register.

In the following sections, we'll show you in more detail how [PRPLOT] and four other plotting functions work, beginning with a description of each of the parameters in the basic plot format.

The Printer Plot Format

Two basic plotting operations, [PRPLOT] and [PRPLOTP], generate plots using the format shown in the previous example. This format is described in detail in figure 6-1. Three other plotting operations generate individual parts of a plot, enabling you to customize your plots according to your needs.

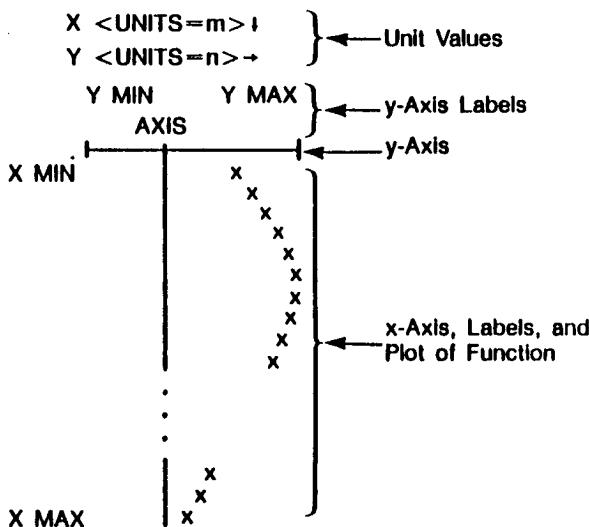

Figure 6-1. The Printer Plot Format.

The unit values are automatically determined by [PRPLOT], [PRPLOTP], and [PRAXIS]. ([PRAXIS] is described later in this chapter). Unit values enable the axis labels to be printed in a shorter form. The X unit value applies to the numbers down the left side of the plot. The Y unit value applies to the numbers across the top of the plot. For example, a unit value of E-2 means the numbers along the axis are expressed in units of 10^{-2} .

The y-axis labels must be specified either from the keyboard or in a program, according to the plotting operation being performed. Y MIN and Y MAX represent the minimum and maximum values of y to be plotted. AXIS represents the position on the y-axis where the x-axis is to be drawn. (If NONE or any other ALPHA characters are specified for AXIS, no x-axis is drawn.)

The x -axis labels must be specified using three numbers; X MIN, X MAX, and X INC. X MIN and X MAX represent the minimum and maximum values of x for which the plot will be drawn. X INC determines the size of the step between values of x : if X INC is positive, x increases in steps of X INC; if X INC is negative, x has that many equal increments from X MIN to X MAX. For example:

Parameters Function plotted at these values

X MIN 0

X MAX 360

X INC 10 0,10,20,30,40,...,360 (10-unit increments)

X MIN 0

X MAX 360

X INC -10 0,36,72,108,144,...,360 (10 equal increments)

The y function values that are plotted are computed by the function program that you provide. It can be *any* program that uses a number in the X-register and returns a corresponding y function value to the X-register.* (If the program returns a y function value greater than Y MAX, that value is plotted at Y MAX. If the program returns a y function value less than Y MIN, that value is plotted at Y MIN.) The function program should not alter registers R₀₀ through R₁₁—these registers are used by the plotting routine. (Register R₀₆ contains a copy of the x value placed into the X-register.)

Plotting with Special Characters

All but one of the plotting operations use register R₀₃ to specify the plotting symbol. If the contents of this register are numeric, the plotting symbol is a small "x". If R₀₃ contains a character representation generated by [BLDSPEC], that special character is used to plot the function. If you do not specify a plotting symbol, clear R₀₃ (by pressing 0 [STO] 03) to ensure that an unwanted symbol is not used.

* When executed from a program, the [PLOT] operation uses either (a) three subroutine levels or (b) two subroutine levels more than the number of subroutine levels in your function program, whichever is greater. (Refer to the owner's manual for your calculator for more information about the allowed number of pending subroutines.)

Interactive Plotting

PRPLOT**R₀₃****plot symbol**

When you execute the **PRPLOT** (print plot) operation, a plot of your programmed function is printed. **PRPLOT** prompts you for the information it needs to construct the axes of the plot. Then it uses the program that you have already stored in program memory (your function program) to plot the actual values.

Registers used by **PRPLOT** include registers R₀₀ through R₁₁. These registers store plotting information. Before you execute **PRPLOT**, you must be sure that storage registers are allocated to at least **SIZE** 012. In particular, the contents of register R₀₃ specify the character (the plot symbol) used to plot the function.

If you allow **PRPLOT** to execute to completion, the display format will be set to **FIX** 4, regardless of the format that was in effect when **PRPLOT** began execution. In addition, flag 12 (Double-Wide) will be cleared.

The **PRPLOT** operation is actually a program that uses normal calculator and module functions. If you wish to look at the program, you can load it into program memory using **COPY**. The **PRPLOT** program requires 77 registers of program memory. Once the **PRPLOT** program is in program memory, you can add new lines and delete existing lines. However, the changes you make cannot be recorded back into your Infrared Printer Module. Instead, you must use the altered program as it is in memory, or record it on a mass storage device. You can print the complete program on your printer. Appendix B contains an annotated listing of **PRPLOT**.

Programmable Plotting

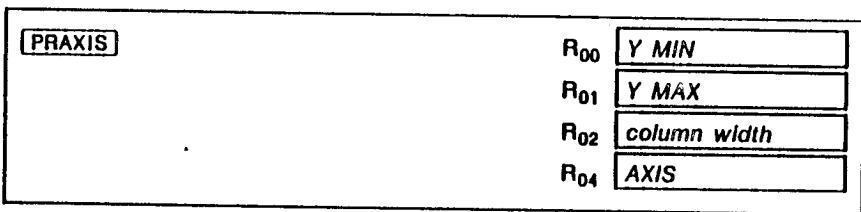

The interactive plotting operation, **[PRPLOT]**, can be executed in a running program. It operates just as it does when executed from the keyboard—by prompting you for the required information. However, another plotting operation, **[PRPLOTP]**, may be more suitable for use in a program. **[PRPLOTP]** generates plots in the same format as **[PRPLOT]**, but does not obtain the plotting information by prompting for it. This feature can be useful for programmed plotting since it does not require you to key in information during program execution.

[PRPLOTP]	R₀₀	Y MIN
	R₀₁	Y MAX
	R₀₃	plot symbol
	R₀₄	AXIS
	R₀₈	X MIN
	R₀₉	X MAX
	R₁₀	X INC
	R₁₁	NAME

[PRPLOTP] obtains the needed plotting parameters from registers **R₀₀** through **R₁₁**. Before executing **[PRPLOTP]**, either from the keyboard or in a running program, store the plotting parameters in the corresponding registers as shown above. **[PRPLOTP]** uses these values to construct the plot, just as **[PRPLOT]** uses them. Be sure your function program does not alter the contents of registers **R₀₀** through **R₁₁**.

[PRPLOTP] is actually a part of the **[PRPLOT]** program. It consists of normal calculator functions and can be copied into program memory using **[COPY]**. It requires 77 registers of program memory.

Plotting a y-Axis

The **PRAXIS** (*print axis*) operation is a part of the **PRPLOT** program. It can be executed separately to print the *y*-axis. When you execute **PRAXIS**, the *y*-axis is scaled, printed, and labeled. This operation can be used for special applications where you want to construct your own plotting routines.

As shown above, the **PRAXIS** operation uses the contents of four registers to construct and label the *y*-axis, as well as to determine the *y*-axis unit value. The column width stored in **R₀₂** specifies the number of dot columns to be spanned by the *y*-axis—it specifies how many columns wide the plot should be. (Your printer has a 166 column line, therefore this parameter can not be greater than 166.) The **PRAXIS** operation modifies the column width parameter in **R₀₂** to include information for plotting the *x*-axis, stores it in **R₀₂**, and displays it in the *X*-register. This revised parameter is suitable for use by two subsequent plotting operations, discussed next. The other plotting parameters are the same as described earlier.

The **PRAXIS** operation uses two subroutine levels in its execution. After the axis has been printed, the two additional levels become available again. **PRAXIS** clears flag 12 (Double-Wide) and leaves the display in **FIX 4** format.

Plotting a Function Value

Two functions, **REGPLOT** and **STKPLOT**, enable you to plot a single numeric value on one line of printer output. By using either of these functions, you have complete control over how data points are plotted. **REGPLOT** uses data storage registers that are compatible with the **PRAXIS** operation. **STKPLOT** uses the stack registers for specifying

50 Plotting

plotting information, making all of the storage registers available for your use. The following information is needed to plot the point:

- Function value.
- Y MIN.
- Y MAX
- Modified Column Width (*nnn.aaa*).
- Plot symbol (if using [REGPLOT]).

The function value is the *y* value to be plotted. Y MIN and Y MAX define the limits of the *y*-axis, as discussed earlier. The modified column width—mentioned in connection with [PRAXIS]—defines both the dot column width of the *y*-axis and the column number for the *x*-axis. The format for the modified column width is *nnn.aaa*. The *nnn* portion specifies how many columns wide the *y*-axis is—the same as with [PRAXIS]. The *aaa* portion (after the decimal point) specifies in which column of the *y*-axis, from 001 to *nnn*, the *x*-axis bar should be printed. (If *aaa* is zero, the *x*-axis bar is automatically printed in the column closest to *y* = 0.) If the modified column width is negative, the *x*-axis bar is not printed. Remember that the modified column width parameter is *automatically* calculated and stored in R₀₂ when [PRAXIS] is executed; if you've executed [PRAXIS] to begin your plot, you do not need to calculate the modified column width when you subsequently execute [REGPLOT] or [STKPLOT].

REGPLOT	X	y value	R ₀₀	Y MIN
			R ₀₁	Y MAX
			R ₀₂	modif. col. width
			R ₀₃	plot symbol

When you execute the [REGPLOT] (*register plot*) function, registers R₀₀ through R₀₃ are used to plot the *y* value in the X-register.

STKPLOT	T	y value
	Z	Y MIN
	Y	Y MAX
	X	modif. col. width

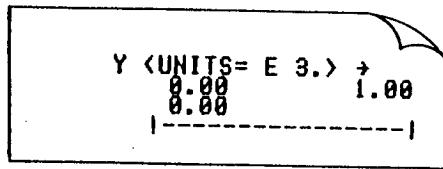

When you execute the [STKPLOT] (*stack plot*) function, plotting information is obtained from the stack registers only—no data storage registers are used. The plotting symbol is automatically a small "x".

You can also print labels for single line plotting using [REGPLOT] and [STKPLOT]. You can create a label by accumulating the label in the print buffer using any of the functions described earlier in this manual. When [REGPLOT] or [STKPLOT] is executed, the buffer is printed immediately to the left of the plot column.

Example: Plotting a y-Axis and a Function Value. In this 2-part example, we'll plot a y-axis and one labeled function value for the function $y = 10x$.

Part 1: Plot a y-axis after defining the plotting parameters as follows: Y MIN = 0, Y MAX = 1000, Column Width = 120, AXIS = 0.
(HP 82240A Thermal Printer: MAN mode)

0 [STO] 00
1000 [STO] 01
120 [STO] 02
0 [STO] 04
[PRAXIS]

Note that [PRAXIS] modified the column width parameter from 120 to 120.0010 and displayed it in the X-register. [PRAXIS] also stored the modified column width parameter in R02.

Part 2: Now plot a single, labeled function value. First, fix the display format to [FIX] 0. Then enter and accumulate a label (an x value) and one character space.

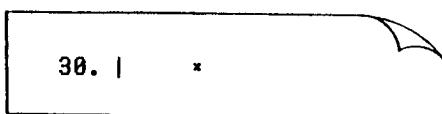

[FIX] 0
30
ACX
ALPHA [SPACE] ALPHA
ACA

Next, return the function value (y-value) by executing 10 [x]. Then enter Y MIN, and Y MAX, and recall the Modified Column Width (automatically calculated by [PRAXIS] in Part 1.).

10 [x]
0 [ENTER]
1000 [ENTER]
RCL 02

Finally, execute the plotting routine, printing the function value.

[STKPLOT]

Programming and Printer Operations

In this chapter we'll cover:

- Printing during program entry.
- Printing during program execution.
- Information on how your calculator displays print functions in a program.

Printing During Program Entry

While you are keying a program into the calculator in PRGM mode, you can use your HP 82240A Thermal Printer to print a record of each line you enter. Simply set the print mode to NORM or TRACE.

Printing During Program Execution

Flag 21 (the Printer Enable Flag)—described in chapter 2—affects printer operation during program execution. Flag 21 does not affect printing functions executed from the keyboard. The following table lists the effects of flag 21 on operations performed in a running program.

FLAG 21		
	SET	CLEAR
Printer Operations	<p>Operation is normal in PRTON mode. PRTOFF MODE displayed in PRTOFF mode. (NON-EXISTENT displayed if no module present.)</p> <p>Display is printed and program execution is not halted in PRTON mode. Display is not printed and program execution is halted in PRTOFF mode. Paper is advanced in PRTON mode. Ignored in PRTOFF mode.</p>	<p>Ignored. (NONEXISTENT displayed if no module present.)</p> <p>Display is not printed and program execution is not halted.</p> <p>Ignored.</p>

Note that by setting flag 21 in PRTOFF mode, execution of **[VIEW]** and **[AVIEW]** cause program execution to be halted and program results to be displayed by the calculator. This feature can be useful to you if you wish to run a program that contains **[VIEW]** or **[AVIEW]** functions when no printer is present. (Program execution is resumed when you execute **[R/S]**).

If the print mode is set to TRACE during program execution, the printer will print the operation on each line along with any intermediate and final results calculated. In this mode, you'll notice that program execution slows significantly to allow the printer to keep up with the execution. TRACE mode execution is a good way to debug your program. However, programs will be executed faster in MAN or NORM mode; in these modes, only output from print functions is printed. Also, in these modes, information is accumulated normally in a program. (In TRACE mode, the contents of the buffer are automatically printed—and are cleared from the buffer—any time that a function name is also printed.)

Almost all print functions discussed in the previous chapters can be executed in a running program—only **[PRP]**, **[LIST]**, and **[CAT]** cannot be programmed. (Be sure that you place in the proper registers any parameters needed by the print function before the function is executed.)

Print Functions in Programs

The print functions discussed in chapters two through six may be entered as part of a program whenever your Infrared Printer Module is installed in a calculator port. When the module is installed, print *functions* in program lines are displayed and printed as normal functions. Print *programs* (PRAXIS, PRPLOT, and PRPLOTP) in program lines are displayed and printed as XROM followed by the program name; for example, XROM PRAXIS.

If your module is disconnected at a later time, print functions in program lines are displayed as XROM functions with two identification numbers. The first number identifies the accessory, (the HP 82242A Module), and the second number identifies the function:

Function	XROM Number	Function	XROM Number
ACA	XROM 29,01	PRX	XROM 29,20
ACCHR	XROM 29,02	REGPLOT	XROM 29,21
ACCOL	XROM 29,03	SKPCHR	XROM 29,22

A

Care, Warranty, and Service Information

Module Care

CAUTION

Always turn off the calculator before installing or removing the module. Failure to do so may result in damage to the calculator or module, or in disruption of system operation.

- Keep the contact area of the module free of obstructions. Should the contacts become dirty, carefully brush or blow the dirt out of the contact area. Do not use any liquid to clean the contacts.
- Store the module in a clean, dry place.
- Keep the Infrared window clean and free of scratches.
- Always turn off the calculator before connecting or disconnecting the module. Follow the procedures described in chapter 1.
- Observe the following temperature specifications:
 - Operating: 0° to 45° C (32° to 113° F).
 - Storage: -20° to 60° C (-4° to 140° F).

Answers to Common Questions

Question: My printer is not printing.

Answer: Your module or your printer may be malfunctioning, but the problem may be much simpler. Refer to the troubleshooting procedure in "Determining If the Module Requires Service" later in this chapter.

Question: My printer is not printing the characters I expect when I execute the **[ACCHR]** function.

Answer: You may be in the wrong character-set mode. Refer to the discussion of **[MAPON]** and **[MAPOFF]** in "Accumulating Characters" in chapter 4.

Question: My program works with an HP 82143A Thermal Printer (or an HP 82162A Thermal Printer) but not with the Infrared Printer Module and HP 82240A Thermal Printer.

Answer: Make sure you are in MAPON mode (by executing **MAPON**). If your program accumulates characters 4, 10, or 27, your program will work properly only if you are in MAPON mode.

The **ADV** function left-justifies some types of information that your program may require to be right-justified.

The HP 82240A Thermal Printer has a 166 column line. If your program contains a **SKPCOL** instruction for 167 or 168 columns, the program will not work.

Refer to appendix E for a discussion of differences between your infrared printing system and the earlier thermal printing systems.

Limited One-Year Warranty

What Is Covered

The module is warranted by Hewlett-Packard against defects in materials and workmanship for one year from the date of original purchase. If you sell your unit or give it as a gift, the warranty is automatically transferred to the new owner and remains in effect for the original one-year period. During the warranty period, we will repair or, at our option, replace at no charge a product that proves to be defective, provided you return the product, shipping prepaid, to a Hewlett-Packard service center.

This warranty gives you specific legal rights, and you may also have other rights that vary from state to state, province to province, or country to country.

What Is Not Covered

This warranty does not apply if the product has been damaged by accident or misuse or as the result of service or modification by other than an authorized Hewlett-Packard service center.

No other express warranty is given. The repair or replacement of a product is your exclusive remedy. **ANY OTHER IMPLIED WARRANTY OF MERCHANTABILITY OR FITNESS IS LIMITED TO THE ONE-YEAR DURATION OF THIS WRITTEN WARRANTY.** Some states, provinces, or countries do not allow limitations on how long an implied warranty lasts, so the above limitation may not apply to you. **IN NO EVENT SHALL HEWLETT-PACKARD COMPANY BE LIABLE FOR CONSEQUENTIAL DAMAGES.** Some states, provinces, or countries do not allow the exclusion or limitation of incidental or consequential damages, so the above limitation or exclusion may not apply to you.

Products are sold on the basis of specifications applicable at the time of manufacture. Hewlett-Packard shall have no obligation to modify or update products once sold.

Consumer Transactions In the United Kingdom

This warranty shall not apply to consumer transactions and shall not affect the statutory rights of a consumer. In relation to such transactions, the rights and obligations of Seller and Buyer shall be determined by statute.

Determining If the Module Requires Service

Your module may require service if any one of the following conditions occurs when you attempt to execute a print function:

- No information is printed.
- Unreadable information is printed.
- Your calculator displays **PRINT ERROR**.

If one of the three conditions described above occurs, use the following procedure to determine if the module requires service:

1. Make sure that the calculator and printer are turned on. Make sure the calculator and printer are positioned within the limits specified by figures 1-2 and 1-3 in chapter 1. If the calculator and printer are turned on and properly positioned, move to step 2.
2. Refer to the description of the print function in this manual. If you are executing the print function correctly, move to step 3.
3. Execute the **RESETP** function, then turn the printer off, then on again. Now try to execute the print function. If you continue to have difficulty, move to step 4.
4. Execute the printer self-test, described on page 14 of the owner's manual for your printer. If your printer fails the self-test, it requires new batteries or service. If your printer passes the self-test, move to step 5. (Do not attempt to send information to the printer during execution of the self-test. This may damage the printer.)
5. Execute the **TESTP** (*module self-test*) function. If the calculator displays **BAD**, the module requires service. If the calculator displays **OK**, try again to execute the print function. If you continue to have difficulty, move to step 6.

6. Turn the calculator off. Turn the printer off. Remove the module from the calculator. Insert it again after several minutes. Turn the calculator and printer on. Execute the **TESTP** function. If the calculator now displays **BAD**, the module requires service. If the calculator displays **OK**, try again to execute the print function. If you continue to have difficulty, the module *or* printer requires service. You will have to return *both* products to a service center.

If this procedure does confirm that service is required, read the following section, "If the Module Requires Service".

If the Module Requires Service

Hewlett-Packard maintains service centers in many countries. These centers will service a module whether it is under warranty or not. There is a charge for service after the warranty period. Modules normally are serviced and reshipped within 5 working days of receipt.

Obtaining Service

- **In the United States:** Send the module to the Calculator Service Center listed on the inside of the back cover.
- **In Europe:** Contact your HP sales office or dealer or HP's European headquarters for the location of the nearest service center. *Do not ship the module for service without first contacting a Hewlett-Packard office.*

Hewlett-Packard S.A.
150, Route du Nant-d'Avril
P.O. Box CH 1217 Meyrin 2
Geneva, Switzerland
Telephone: (022) 82 81 11

- **In other countries:** Contact your HP sales office or dealer or write to the U.S. Calculator Service Center (listed on the inside of the back cover) for the location of other service centers. If local service is unavailable, you can ship the module to the U.S. Calculator Service Center for repair.

All shipping, reimportation arrangements, and customs costs are your responsibility.

Service Charge

There is a standard repair charge for out-of-warranty service. The Calculator Service Center (listed on the inside of the back cover) can tell you how much this charge is. The full charge is subject to the customer's local sales or value-added tax wherever applicable.

Calculator products damaged by accident or misuse are not covered by the fixed service charges. In these cases, charges are individually determined based on time and material.

Shipping Instructions

If your module requires service, ship it to the nearest authorized service center or collection point. (You must pay the shipping charges for delivery to the service center, whether or not the module is under warranty.) Be sure to:

- Include your return address and description of the problem.
- Include proof of purchase date if the warranty has not expired.
- Include a purchase order, check, or credit card number plus expiration date (Visa or MasterCard) to cover the standard repair charge. In the United States and some other countries, the serviced module will be returned C.O.D. if you do not pay in advance.
- Ship the module in adequate protective packaging to prevent damage. Such damage is not covered by the warranty, so we recommend that you insure the shipment.
- Pay the shipping charges for delivery to the Hewlett-Packard service center, whether or not the module is under warranty.

Warranty on Service

Service is warranted against defects in materials and workmanship for 90 days from the date of service.

Service Agreements

In the U.S., a support agreement is available for repair and service. Refer to the form in the front of the manual. For additional information, contact the Calculator Service Center (see the inside of the back cover).

Regulatory Information

Radio Frequency Interference

U.S.A. The HP 82242A Infrared Printer Module generates and uses radio frequency energy and may interfere with radio and television reception. The module complies with the limits for a Class B computing device as specified in Subpart J of Part 15 of FCC Rules, which provide reasonable protection against such interference in a residential installation. In the unlikely event that there is interference to radio or television reception (which can be determined by turning the calculator off and on with the module installed), try:

- Reorienting the receiving antenna.
- Relocating the printing system with respect to the receiver.

For more information, consult your dealer, an experienced radio/television technician, or the following booklet, prepared by the Federal Communications Commission: *How to Identify and Resolve Radio-TV Interference Problems*. This booklet is available from the U.S. Government Printing Office, Washington, D.C. 20402, Stock Number 004-000-00345-4. At the first printing of this manual, the telephone number was (202) 783-3238.

Air Safety Notice (U.S.A.)

The HP-41C, CV, and CX calculators, the HP 82242A Module and the HP 82240A printer comply with the requirements of RTCA (Radio Technical Commission for Aeronautics) Docket 160B, Section 21. Many airlines permit the use of calculator products in flight based on such a qualification. However, before boarding a flight, check with an airline representative regarding use of these products in flight.

B

Annotated **PRPLOT** Program Listing

Following is a listing of the **PRPLOT** plotting program. With the Infrared Printer Module installed in your calculator, you can load this program into the calculator's program memory using the **[COPY]** function. The **PRPLOT** program requires 77 registers of program memory. Refer to the owner's manual for your calculator for more information about **[COPY]**.

C

Storage Space In the Print Buffer

The print buffer has 200 bytes of storage space. The buffer can fill and overflow if:

- Long strings of text, or text and graphics, are accumulated without execution of **[ADV]** or **[PRBUF]**.
- Information is sent to the printer too rapidly (by setting **[DELAY]** too short).

In either case, information may be lost. If this happens, the "Z" character is printed, and your printer may require a linefeed command (**[ADV]** or **[PRBUF]**) to resume printing.

The following table summarizes the space occupied in the print buffer by printer operations. This table will be helpful to you if you are accumulating a long string of information and wish to keep account of how much space the string occupies in the buffer.

Operation	Number of Bytes
[ACA]	The number of characters in the ALPHA register.
[ACCHR]	1
[ACCOL]	<ul style="list-style-type: none"> ■ $N + 2 \times [1 + \text{INT}\{(N - 1)/26\}]$, where N is the number of consecutive [ACCOL] executions. ■ N, if executed as part of a specified length graphics sequence.
[ACSPEC]	Same as 7 consecutive [ACCOL] commands.
[ACX]	The number of characters in the calculator display, plus 1 for the leading sign.
[SKPCHR]	The number value specified in the X-register.
[SKPCOL]	<ul style="list-style-type: none"> ■ $3 + \text{INT}\{(N - 1)/7\} + (N - 1)\text{MOD}7$, where N is the number value specified in the X-register. ■ N, if executed as part of a specified length graphics sequence.
[STARTU],	2
[STOPU]

Some points to note:

- Characters 1, 2, 6-9, 11, 14, 15, 17, and 18 from the standard character set of the HP 82143A Thermal Printer and HP 82162A Thermal Printer are not included in standard character set of the HP 82240A Thermal Printer. In MAPON mode, the “_” character is substituted for these characters.
- In MAPON mode, character 124 is obtained from the standard character set of the HP 82162A Thermal Printer. (Character 124 in the standard character set of the HP 82143A Thermal Printer is a different character.)

* In earlier HP 82240A Thermal Printers, characters 13, 124, and 127 are replaced with the “_” character in MAPON mode. To determine if your printer replaces characters 13, 124, and 127 with “_”, perform the printer self-test. (See pages 14-15 of the owners manual for your printer for instructions on how to perform the printer self-test.) If your printer does not print a capital letter on the last line of the character printout, then “_” will be substituted for characters 13, 124, and 127.

- In MAPOFF mode character codes 4, 10, and 27 are *control codes*. When you accumulate these codes in the buffer of your printer, a *printer operation* is performed: accumulation of character code 4 causes a linefeed that leaves the printhead on the right edge of the paper, accumulation of character code 10 causes a line feed that leaves the printhead on the left edge of the paper, and accumulation of character code 27 starts an escape sequence. Refer to pages 22 and 23 in the owner's manual for your HP 82240A Thermal Printer for additional information. Note that a program written for the HP 82143A Thermal Printer or the HP 82162A Thermal Printer that accumulates characters 4, 10, or 27 during program execution *will not execute properly* in MAPOFF mode! You must edit such a program and substitute a new character code if you wish to execute the program in MAPOFF mode.

If You've Used an HP Thermal Printer...

The print functions and system control functions of the HP 82242A Infrared Printer Module/HP 82240A Thermal Printer printing system are similar to those of two earlier HP thermal printing systems, the HP 82143A Thermal Printer and the HP 82160A HP-IL Module/HP 82162A Thermal Printer. If you have worked with either of these two systems, you may wish to use this appendix as your primary reference guide for operation of your new infrared system.

Common Flags and Functions

Common Flags

Calculator flags 12, 13, and 21 control printer operations in your new printer system as they do in the earlier thermal printer systems. Their effects are summarized in table 2-1.

Common Functions

The following print functions from the earlier printing systems have been implemented in your infrared system. In some cases, your new system executes these functions differently, as noted.

Function	Differences In Execution
ACA	
ACCHR	ACCHR accepts character codes up to 255.
ACCOL	
ACSPEC	
ACX	
ADV	<p>ADV <i>left-justifies</i>:</p> <ul style="list-style-type: none"> Any character string greater than 27 total bytes. Strings that contain information accumulated with the ACCOL or ACSPEC functions, unless the ACCOL or ACSPEC-accumulated information <i>begins</i> the string. Any ACCOL- or ACSPEC-accumulated string that contains mode change instructions (STARTU, STOPU, SF 12, CF 12).
AVIEW	
BLDSPEC	
CAT	
FMT	FMT cannot format any string that ADV left-justifies.
LIST	Program listings are printed left-justified in NORM mode. A <i>triangular</i> pointer is printed at each label.

Function	Differences In Execution
<input type="checkbox"/> PRA <input type="checkbox"/> PRAXIS <input type="checkbox"/> PRBUF <input type="checkbox"/> PRFLAGS <input type="checkbox"/> PRKEYS <input type="checkbox"/> PROMPT <input type="checkbox"/> PRP <input type="checkbox"/> PRPLOT <input type="checkbox"/> PRPLOTP <input type="checkbox"/> PRREG <input type="checkbox"/> PRREGX <input type="checkbox"/> PRS <input type="checkbox"/> PRSTK <input type="checkbox"/> PRX <input type="checkbox"/> REGPLOT <input type="checkbox"/> SKPCHR <input type="checkbox"/> SKPCOL <input type="checkbox"/> STKPLOT <input type="checkbox"/> VIEW	<p>Programs are printed left-justified in NORM mode. A triangular pointer is printed at each label.</p> <p>The maximum skip column number is 166. (The HP 82240A Thermal Printer has a 166 column line. The earlier systems have a 168 column line.)</p>

Additional Functions

Your infrared printing system executes the following functions *not available* in the earlier thermal printing systems. Note that a program containing any of the functions discussed in this section will not work with the earlier thermal printing systems.

Turning Print Functions On and Off

When you install the Infrared Printer Module and turn your calculator on, or when you execute the **[PRTON]** or **[RESETP]** functions, print functions are executed normally. When you execute the **[PRTOFF]** function, all printing operations are suppressed. Refer to "Turning Print Functions On and Off" in chapter 2, and "Printing During Program Execution" in chapter 7, for more information.

Setting the Print Mode

The print mode is selected by setting the appropriate state of flags 15 and 16, or by executing the **[MAN]**, **[NORM]**, or **[TRACE]** function. Refer to table 2-2 and "Setting the Print Mode", in chapter 2, for more information.

Remapping the Character Set

When you install the Infrared Printer Module and turn your calculator on, or when you execute the **[MAPON]** or **[RESETP]** functions, the HP 82240A Thermal Printer's standard character set is *remapped*. It becomes compatible with the HP 82143A Thermal Printer and HP 82162A Thermal Printer's standard character set. The **[MAPON]** function enables you to execute programs that have been written for the earlier thermal printer systems and utilize their extended character set. When you execute the **[MAPOFF]** function, character remapping is turned off. The character set in MAPOFF mode matches that in the HP 82240A Thermal Printer owners manual, pages 18-19. Refer to 'Accumulating Characters' in chapter 4, and appendix D, for more information.

Underlining Characters

When you execute the **[STARTU]** function, a "start underlining" instruction is accumulated in the print buffer; all subsequently printed characters are underlined until you execute the **[STOPU]** function or turn your printer off, then on. Refer to 'Accumulating Underline' in chapter 4 for more

Setting the Delay

The **[DELAY]** function enables you to set the time that your calculator waits between sending lines of information to your printer. Refer to "Setting the Delay" in chapter 2 for more information.

Resetting the System Control Flags and Functions

When you execute the **[RESETP]** function, the system control flags and functions are returned to their default state. Refer to "Functions That Control Printer Operations" in chapter 2 and "Printing the Contents of the Print Buffer" in chapter 4 for more information.

Testing the Module

When you execute the **[TESTP]** function, the module performs a self-test. Refer to "Determining If the Module Requires Service" in appendix A.

Using Control Characters

In MAPOFF mode, characters 4, 10, and 27 are control characters. Refer to "Graphics in MAPOFF Mode" in chapter 5, and appendix D for more information.

Features Not Available

Your infrared printing system does *not* have the following features available in the earlier thermal printing systems:

From the Standard Character Set

Characters 1, 2, 6-9, 11, 14, 15, 17 and 18 from the earlier printers' standard character set are not available in the HP 82240A Thermal Printer's standard character set. In MAPON mode, a '_' is substituted. Refer to appendix D for additional information.

Print Mode Switch

The HP 82240A Thermal Printer does not have the print mode switch found on the earlier thermal printers. It is replaced by the **[MAN]**, **[TRACE]**, and **[NORM]** functions (and, alternately, flags 15 and 16) described previously in this appendix and in chapter 2.

Paper Advance Button

The HP 82240A Thermal Printer's paper advance button will advance the paper only. (The paper advance button on the earlier thermal printers also enters the **[ADV]** function into a program when your calculator is in program mode.)

Paper Detection

The infrared printing system does not detect the "out-of-paper" condition in the HP 82240A Thermal Printer.

Bar Code Printing

The Infrared Printer Module does not support bar-code printing functions.

Error Messages

This appendix contains a list of error messages that you may encounter during the operation of your printer system.

For most error conditions, the function being attempted is not performed. However, for those conditions and functions indicated by * below, the operation may be partially performed.

Error	Functions	Meaning
ALPHA DATA	-all-	ALPHA characters are in a register where a number is required—either in a stack register or a data storage register.
DATA ERROR	[ACCHIR] [ACCOL] }	$ x > 255.$
	[BLDSPEC]	$ x > 127.$
	[DELAY]	$ x > 1.9.$
	[PRAXIS]	YMAX \leq YMIN, AXIS > YMAX, AXIS < YMIN, or $lnnnl > 166$.
	*[PRPLOT]	XMAX \leq XMIN, YMAX \leq YMIN, AXIS > YMAX, or AXIS < YMIN.
	[PRREGX]	$ x > 999.$
	[REGPLOT] [STKPLOT] }	YMAX \leq YMIN, $nnn < 10$, or $lnnnl > 166$.
	[SKPCHR]	$ x > 24.$
	[SKPCOI]	$ x > 166.$

NONEXISTENT	-all-	The HIP 82242A Module is not installed.							
		<table><tr><td>PRPLOT</td><td rowspan="3">}</td><td>One or more of the specified registers has</td></tr><tr><td>PRPLOTP</td><td>not been allocated. Increase allocation to</td></tr><tr><td>PRAXIS</td><td>SIZE 12.</td></tr></table>	PRPLOT	}	One or more of the specified registers has	PRPLOTP	not been allocated. Increase allocation to	PRAXIS	SIZE 12.
PRPLOT	}	One or more of the specified registers has							
PRPLOTP		not been allocated. Increase allocation to							
PRAXIS		SIZE 12.							
		<table><tr><td>*PRPLOTP</td><td rowspan="3">}</td><td>Specified program or function program</td></tr><tr><td>*PRPLOT</td><td>does not exist. Check program name.</td></tr><tr><td>PRP</td><td></td></tr></table>	*PRPLOTP	}	Specified program or function program	*PRPLOT	does not exist. Check program name.	PRP	
*PRPLOTP	}	Specified program or function program							
*PRPLOT		does not exist. Check program name.							
PRP									
		<table><tr><td>PRP</td><td>An attempt was made to list a ROM</td></tr><tr><td></td><td>function that was not written in user</td></tr><tr><td></td><td>code.</td></tr></table>	PRP	An attempt was made to list a ROM		function that was not written in user		code.	
PRP	An attempt was made to list a ROM								
	function that was not written in user								
	code.								
	*PRREGX	Specified registers exceed highest data storage register. Check <i>bbb.ooo</i> format in X-register.							
PRINT ERROR	*-all-	Module may be malfunctioning. Refer to "Determining If the Module Requires Ser- vice" in appendix A.							
PRIVATE	-all-	An attempt was made to list, trace, edit, or view a private program.							
PRTOFF MODE	-all-	Print operation attempted in PRTOFF mode.

[STARTU], 31, 81
[STKPLOT], 50, 80

STOPU mode
 definition, 31
 set with **[RESETP]**, 31, 34
[STOPU], 31, 81

T

[TESTP], 57, 81

Thermal printer systems, earlier, 10, 78-82

TRACE mode
 definition, 12
 set with **[TRACE]**, 14
[TRACE], 14, 80

U

Underline modes
 definition, 31, 81
 effect of **[RESETP]**, 31, 34
STARTU and **STOPU**, 31

Unit values, in plots, 45

V

[VIEW], 17, 80

W

Warranty information, 56-57

X

x-axis labels, specifying in plot, 46
XROM numbers, 54

Y

y-axis labels, specifying in plot, 45

Function Index

Page numbers in **bold** type indicate primary references; page numbers in normal type indicate secondary references.

Function	Description	Page
[ACA]	Accumulate contents of ALPHA register into print buffer.	27, 78
[ACCHR]	Accumulate standard character into print buffer.	29, 78
[ACCOL]	Accumulate graphics column into print buffer.	37, 78
[ACSPEC]	Accumulate special character into print buffer.	39, 78
[ACX]	Accumulate contents of X-register into print buffer.	28, 78
[ADV]	Print contents of print buffer and advance paper one line.	18, 32, 40, 41, 78
[AVIEW]	View and print contents of ALPHA register.	18, 78
[BLDSPEC]	Build special character in X- and Y-registers.	38, 78
[CAT]	View and print specified catalog. (Not programmable.)	18, 78
[DELAY]	Set time that calculator waits between sending lines of information to printer.	15, 80
[FMT]	Specify formatting option for printed output.	33, 40, 41, 78
[LIST]	List program lines. (Not programmable.)	22, 78

Function	Description	Page
MAN	Set print mode to MAN (<i>manual</i>).	14, 79
MAPOFF	Set character-set mode to MAPOFF.	29-30, 80
MAPON	Set character-set mode to MAPON.	29, 80
NORM	Set print mode to NORM (<i>normal</i>).	14, 79
PRA	Print contents of ALPHA register.	19, 79
PRAXIS	Print and label y-axis of plot.	49, 79
PRBUF	Print contents of print buffer left-justified.	33, 79
PRKEYS	Print list of reassigned keys.	24, 79
PROMPT	View and print ALPHA prompt.	18, 79
PRP	Print program. (Not programmable.)	22, 79
PRPLOT	Plot function interactively.	47, 79
PRPLOTP	Plot function noninteractively.	48, 79
PRREG	Print contents of all storage registers.	19, 79
PRREGX	Print contents of specified storage registers.	20, 79
PRΣ	Print contents of statistics registers.	20, 79
PRSTK	Print contents of X-, Y-, Z-, T-registers.	19, 79
PRTOFF	Suppress all printing operations.	13, 79
PRTON	Execute printing operations normally.	13, 79
PRX	Print contents of X-register.	19, 79
REGPLOT	Plot single function value using storage registers.	50, 79
RESETP	Reset system control flags and functions.	16, 34, 80
SKPCHR	Accumulate skipped characters into print buffer.	30, 79
SKPCOL	Accumulate skipped dot columns into print buffer.	38, 79
STARTU	Underline all subsequently printed information.	31, 80
STKPLOT	Plot single function value using stack registers.	50, 79
STOPU	Stop underlining all subsequently printed information.	31, 80
TESTP	Execute printer self-test.	57, 80
TRACE	Set print mode to TRACE.	14, 79
VIEW	View and print specified register.	17, 79

Contacting Hewlett-Packard

For Information About Using the Module. If you have questions about how to use the module, first check the Table of Contents, the Subject Index, and the Function Index. If you can't find an answer in the manual, you can contact the Calculator Technical Support department:

Hewlett-Packard
Calculator Technical Support
1000 N.E. Circle Blvd.
Corvallis, OR 97330, U.S.A.

(503) 757-2004
8:00 a.m. to 3:00 p.m. Pacific time
Monday through Friday

For Service. If your module doesn't seem to work properly, see appendix A to determine if the module requires service. Appendix A also contains important information about obtaining service. If your module does require service, mail it to the Calculator Service Center:

Hewlett-Packard
Calculator Service Center
1030 N.E. Circle Blvd.
Corvallis, OR 97330, U.S.A.

(503) 757-2002

For Information About Hewlett-Packard Dealers, Products, and Prices. Call the following toll-free number:

(800) 752-0900
