

This document was scanned from a much earlier photocopy which already had several issues:

- Some text pages were cut off slightly at the sides.
- The schematics were photocopied on to 11x17 pages. However, the original schematics may have been on sheets larger than 11 x17 and so the collection of schematics appears incomplete.

This file shows the pages as received and is the best scan available at this time. We hope it will be useful.

## INTRODUCTION

This manual contains technical information describing the -hp-, preprogrammed, desktop calculators; the Model 5, the Model 46, and the Model 81. We have presumed that this manual will be used only by qualified -hp- service personnel located at designated repair centers. We have also assumed that those personnel who are using the manual have, and are trained to use, the special test equipment described in Chapters 5 and 6.

## GENERAL DESCRIPTION

The -hp- preprogrammed, desktop calculators are expanded versions of the smaller, hand-held calculators — the Models 35, 45, and 80. The primary difference between the hand-held and the corresponding desktop calculators are the SEIKO printer and the display being optional. The Model 5 (9805A) is also somewhat different, in that it is intended for use only in the field of statistics. The Model 46, like the Model 45, is primarily a scientific and engineering machine. The Model 81, like the Model 80, is designed for use in business applications.

### General Specifications

Table 1-1 lists the general specifications of each calculator for packaging and shipping purposes.

## OPTIONS AND ACCESSORIES

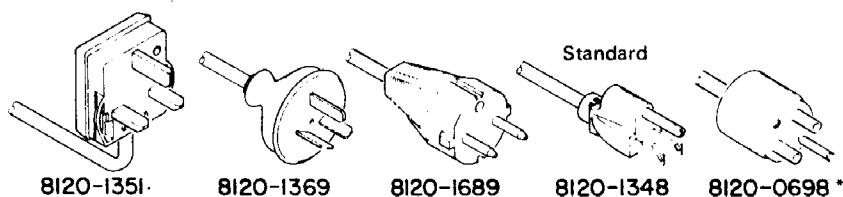

Both the Model 46 and the Model 81 have an optional display (Opt. 001). The Model 81 may also have a 'buffered keyboard' with or without a display; Opt. 002 is a buffered keyboard without a display, while Opt. 003 includes a display. The buffered keyboard allows the user to enter keys while the calculator is busy performing a previous input. Up to 64 keys may be pressed, while the calculator is busy, before subsequent inputs are ignored.

The Model 5 is available in five different configurations:

- The basic Model 5 is Option 001, which contains a printer and statistics keyblock, but has no display.
- Option 2 adds a display to the basic machine.
- Option 3 includes a display and the capability of controlling a 9862A Plotter; the plotter must be ordered separately.
- Option 4 is an Option 2 calculator with the addition of 30 data storage registers and a statistics Programmable Read-Only-Memory (PROM).
- Option 5 adds plotter control capability to Option 4; again, the plotter must be ordered separately.

### Power Cords

Various power cords are available for the calculator. Their descriptions and -hp- part numbers are shown in Figure 1-1.

\* UL approved for use in the United States with Calculators set for either 220V or 240V operation.

Figure 1-1. Power Cords

## CHAPTER 2

### GENERAL PRINCIPLES OF OPERATION

#### INTRODUCTION

The information contained in this chapter describes the basic principles which govern the operation of the Models 46 and 81 and the 9805A. Figure 2-5, a block diagram of the calculator circuits, should be used while the information is being studied.

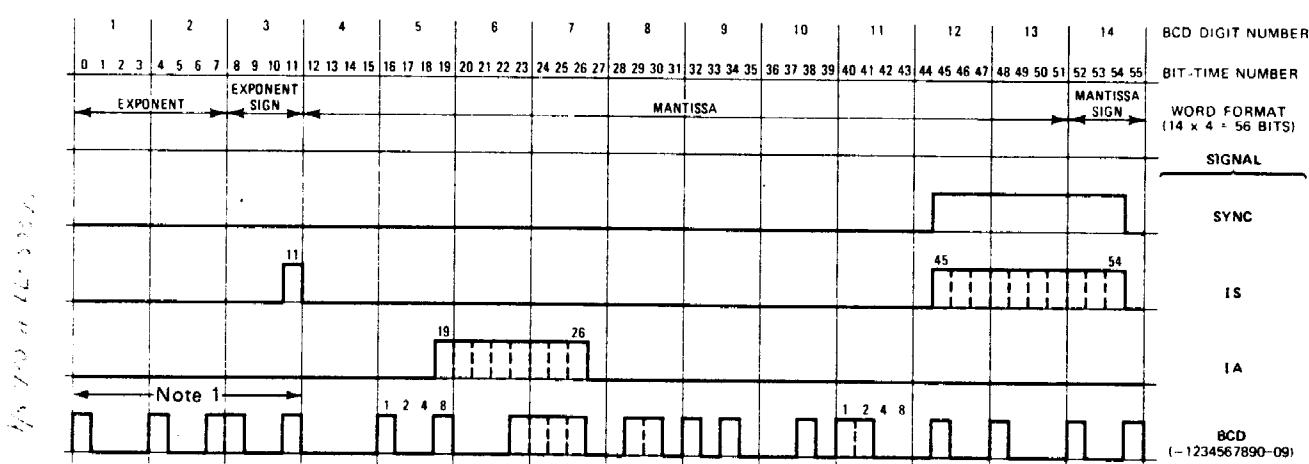

#### SYSTEM ORGANIZATION

Each of the calculators contains four MOS/LSI (metal-oxide-semiconductor/large-scale-integration) circuits: read-only-memories (ROMs), an arithmetic and register circuit (A&R), a control and timing circuit (C&T), and an I/O processor circuit. Also, three bipolar circuits are utilized: a two-phase clock driver, an LED anode driver/clock generator, and an LED cathode driver.

Basically, each calculator is assembled on three printed circuit boards: the keyboard, the mother board, and the father board. The mother board contains the MOS logic and power supplies. In the Model 5, the A&R and I/O processor circuits are contained on the father board. The father board contains the clock circuits and, if the display option is installed, the display and display-driver circuits. One of two different father boards must be used in each instrument: the father board or the display board. The display board is a father board with the additional display circuits. The Model 81 display and father boards may also contain the buffered keyboard circuits. The keyboard contains the keys and switches for the instrument.

The Model 5 may contain additional circuit boards, depending upon the option installed: the statistics keyblock, which is basically an additional keyboard with the ROMs and logic required to implement its use; the plotter interface, which enables control of the plotter; the data storage board, which provides 30 additional data storage registers for the calculator; the programmable-read-only-memory board (PROM), which contains keycodes for the execution of particular statistical functions. With the exception of the PROM boards, each of the optional assemblies contain the ROMs and logic required to implement its use.

Each calculator is organized on a digit-serial, bit-serial basis. This organization minimizes the number of connections on each chip, thereby saving area and cost and improving reliability. Each word consists of 14 binary-coded-decimal (BCD) digits, and thus is 56 bits long. Ten of the 14 digits are allocated to the mantissa of each number, one is for the mantissa sign, two are for the exponent, and one for the exponent sign (see Figure 2-1). The decimal-point information is included in one of the digit's display information.

NOTE 1: Negative exponents are handled by the system in the ten's-complement notation; positive exponents are handled in the normal BCD form (see Figure 3-4 in Chapter 3).

Figure 2-1. The System Bus-signals

## CHAPTER 2

### GENERAL PRINCIPLES OF OPERATION

Three main bus lines connect the MOS logic (see Figures 2-1 and 2-5). One carries a word synchronization signal (SY) which is generated by a 56-state counter on the C&T circuit. On another bus, instructions (Is) are transmitted serially from the ROMs to the C&T, A&R, and to other ROMs. The I/O processor selects one of two instruction sets, thus enabling one instruction to have two different meanings. Since one instruction can be used for two different operations the instruction set of the calculator is effectively doubled. The third bus signal, called word-select (WS), is a gating signal generated either by the C&T or by one of the ROMs. WS enables the A&R for a portion of a word time, thus allowing operations on only part of a number (from 0 to 14 digits, but never a portion of a digit), such as the mantissa or the exponent (see Figure 2-2).

#### Control and Timing Circuit

The C&T performs the major non-arithmetic (i.e., housekeeping) functions in the calculator. These functions include interrogating the keyboard, keeping a record of the system status reports, synchronizing the system, and modifying instruction addresses.

The keyboard is arranged in a five-column, eight-row (seven in the Model 5) matrix. It is scanned continually by the C&T circuit. When contact is made between a row and a column by pressing a key, a code, corresponding to that row and column, is stored in the C&T. Then, at the appropriate time, the code is transmitted over the instruction address (Ia) line to the ROMs. This code is the starting address of a program in ROM to service that key. Key bounce and lockout are handled by delays programmed into the ROMs. The Model 5 keyblock is also scanned by the C&T. When a keyblock is pressed, a signal is generated on the mother board to inform the C&T that a keyblock ROM is required to service that key. The I/O processor is then used to control the flow of data to ensure that the appropriate keyblock ROM is accessed using the keycode from the C&T.

In all digital systems, status bits or flags are used to maintain a record of past events. In this system, there are two status bits, all located in the C&T. They can be set, reset, or interrogated by microinstructions from the ROMs. The A&R also stores data which indicates the user-selected calculator modes of operation (e.g., display mode).

ROM addresses are updated in the C&T and sent serially to the ROMs over the Ia line. During execution of a branch instruction, the appropriate signal — arithmetic carry or status bit — is tested to determine whether the incrementer address or the branch address should be selected next.

A powerful feature of the serial organization is the ability to operate on just a single digit of a number as it flows through the arithmetic unit. The C&T contains a pointer register and a word-select circuit which issues a word-select signal (WS) corresponding to the digit(s) being operated on (see Figure 2-2). The value of the pointer register can be incremented, or decremented by ROM instructions.

#### Read-Only-Memory

Preprogrammed mathematical routines are stored in the ROM circuits, each of which contains 256 instructions of 10 bytes each (2560 total bits per ROM). A specific select-code is assigned to each ROM, and only one ROM can be active at any time. When a ROM-select instruction is issued, a decoder inside of each ROM checks the select-code field of the instruction. In case of a match, the selected ROM's output is switched on, and all other ROM's outputs are switched off. Therefore, each ROM must 'listen' to all instructions on the Is bus.

A timing circuit on each ROM is synchronized to the SYNC signal issued by the C&T as the calculator is switched on. This circuit then keeps the ROM circuit running synchronously with the rest of the system.

A ROM address register on each ROM receives the address sent out by the C&T on the Ia bus. The ROM then places the corresponding instruction on the instruction bus, Is, provided the ROM is active (i.e., previously selected to output instructions).

The ROM circuit also issues word-select signals, WS, for certain arithmetic instructions.

Since all ROMs in the system are connected in parallel, space is conserved by placing four ROMs in one package, called quad-ROMs. This requires, however, not only ROM-select decoding circuits for the individual ROMs, but also group-select decoding for pairs of quad-ROMs (two quad-ROMs or eight single-ROMs constitute one ROM group).

## CHAPTER 2

### GENERAL PRINCIPLES OF OPERATION

#### Arithmetic and Register Circuit

The Arithmetic and Register Circuit (A&R) executes instructions coming in bit-serially on the IS bus. All arithmetic instructions must be enabled by WS, the word-select signal. Data to be displayed is sent to the LED anode-driver on five lines, A thru E, and the START (SRT) line. One CARRY line transfers carry/borrow information back to the C&T. The BCD output is bidirectional; BCD digits are transferred into and out of the A&R to the I/O processor and data storage circuits.

The A&R circuit is divided into five areas: an instruction storage and decoding circuit, a timing circuit, seven 56-bit registers, an adder-subtractor, and a display decoder.

Three of the seven registers are working registers (see Figure 2-5). One of these and three of the remaining four registers form a four-register stack. The seventh register is an independent register for storage of calculator mode information (e.g., display mode). There are numerous interconnections between registers to allow for such instructions as exchange, transfer, rotate stack, and so on. An advantage of the bit-serial structure is that these interconnections require only one gate per data line.

Transfers into or out of the stack or the mode register are always whole-word (56-bit) transfers. All other arithmetic instructions are controlled by the word-select (WS) signal. For example, it's possible to interchange only the mantissa and sign of two registers, (see Figure 2-2) or to add any two corresponding digits of two registers.

The adder-subtractor computes the sum or difference of two decimal numbers. It has two data inputs, storage for carry or borrow, and sum and carry/borrow outputs. For the first three clock times, the addition is strictly binary. At the fourth clock time, the binary sum is checked, and if the answer is more than 1001 (nine), then the sum is corrected to decimal by adding 0110 (six). For example, the BCD equivalent of twelve (1100) is twelve (1100) + six (0110) or two (0010) with a carry to the next significant digit. The result is then entered into the last four bits of the receiving register and the carry is stored. A similar correction is done for subtraction. Carry information is always transmitted, but is recorded by the C&T only at the last bit time of the word-select signal.

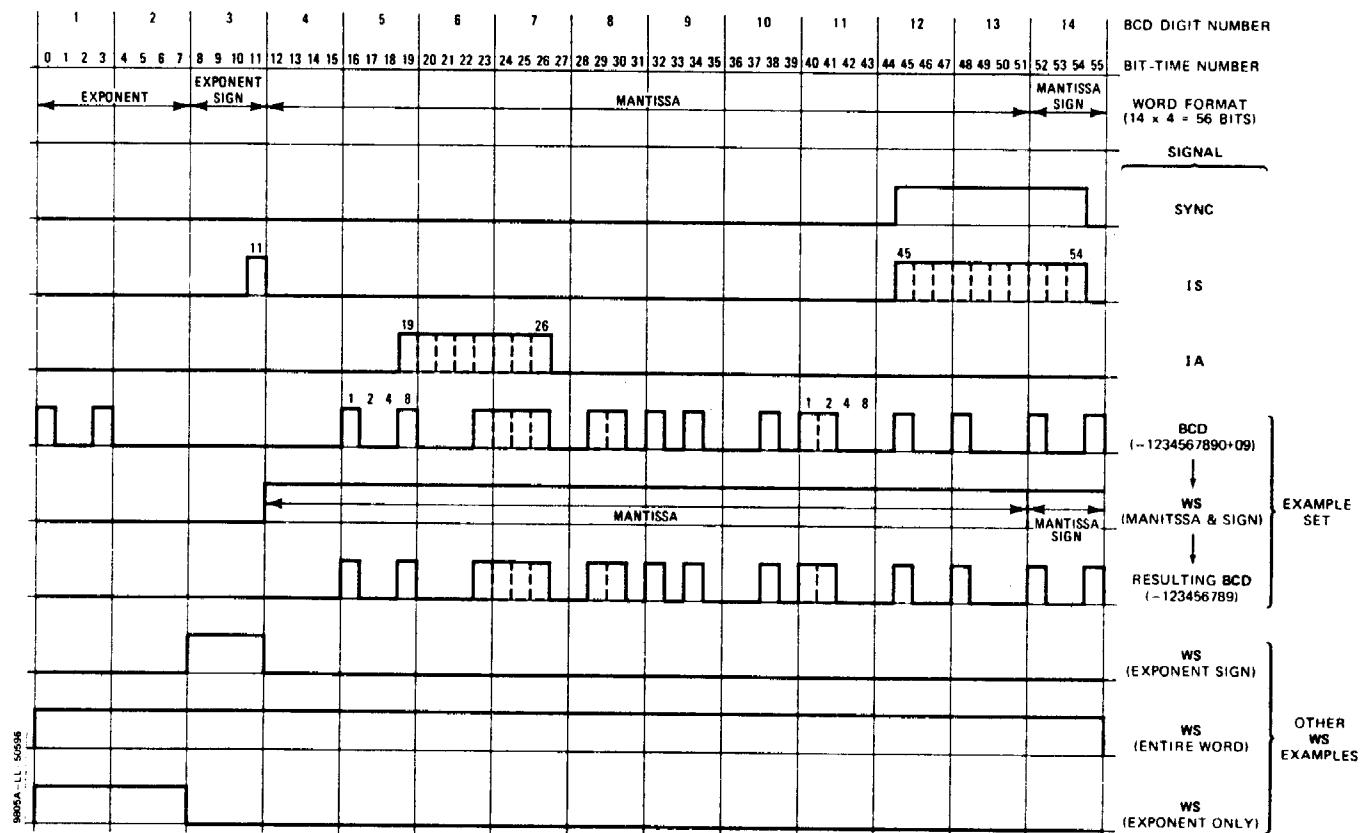

Figure 2-2. An Example of the WS Signal on BCD Data Being Operated On

## CHAPTER 2

### GENERAL PRINCIPLES OF OPERATION

#### I/O Processor Circuit

The I/O processor circuit has four primary functions in the calculator system:

- To expand the basic instruction set, thereby increasing the number of microinstructions available for the system.
- To provide additional timing and drive signals for the implementation of the SEIKO printer.
- To provide a binary arithmetic-unit for the system.
- To interface to the optional Model 5 circuits, which may also contain ROMs.

In this system, the Is bus is interrupted and divided into two separate lines: Is1 and Is2. The processor controls which line is being used. It is set to enable the Is1 line — the instruction line to the C&T and A&R — when power is switched ON. The processor is, however, constantly monitoring the instructions on the Is1 line. When a mainframe F instruction requires the use of the alternate instruction set, Is2, that set is enabled and instructions to the C&T and A&R circuits are disabled. The C&T and A&R are still operating, but are receiving no-operation instructions (all bits are low) on the Is1 bus. The processor performs the operations specified by the incoming ROM instructions until an instruction is received, at which time instructions are again enabled to the C&T and A&R (see Figure 2-3).

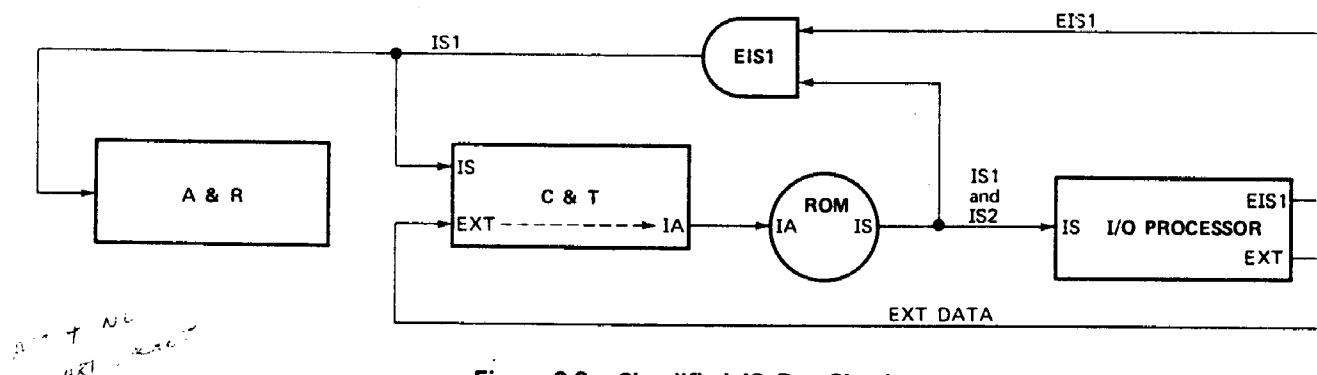

Figure 2-3. Simplified IS Bus Circuit

The processor, together with an external decoder circuit, provides the signals which enable the ROMs on the optional assemblies. Other signals are output from the decoder; these signals control the flow of data from the PROM and printer interface assemblies.

The SEIKO printer is a 'flying drum' impact printer; the printer characters are located on a cylinder (the drum) that is continuously rotating. Printing occurs when a flat-faced hammer strikes the ribbon, forcing it against the paper which is positioned immediately in front of the rotating drum.

The print-drum is organized into 18 columns and 13 rows; each row passes under the hammers approximately every 1 msec (see Figure 2-4). For printing to occur, the processor must actuate the desired printer electro-magnets so that the necessary hammers strike the drum while the specified character, in each column, is passing through the printing area. To accomplish this, the processor correlates timing information from the calculator with print-drum position signals from the printer. Using instructions from the ROMs, it outputs the correct signals to actuate the solenoids at the correct time.

The processor 'remembers' which row of characters is behind the hammers by incrementing a counter each time a row passes through the printing area; the counter is reset after the last row passes through the area. The ROM instruction store 18 hexadecimal digits (one for each column) in two 14-digit shift-registers before the printing process begins. (Of the 28 available digit-positions, 10 are not used during the printing operation.) One register is in the A&R, the other in the processor. Then, after a print instruction is received, the processor actuates the hammer in each column when the hexadecimal number stored in the digit position for that column matches the number in the counter. Printing will occur in any column in which the two numbers do not match. Spaces are provided when the hexadecimal number stored in the associated digit position is 13 or greater. After the drum finishes one complete rotation, the processor receives an instruction to advance the paper one line.

The processor is also used to interface to the Model 5 optional assemblies by providing 10 output and 8 input/output data-lines to those assemblies. Also, by implementing an additional decoder circuit, the ROMs on the optional assemblies are enabled and the I/O-data control lines are provided. The binary arithmetic unit is mostly used in conjunction with the plotter interface assembly. When use of a PROM is necessary, the processor circuit uses ROM instructions to provide the initial PROM address, then increments the address after the keycode from the previous address has been completely serviced. The PROM output keycode is transferred, during the correct system bit times, from the processor circuit to the C&T circuit on the external (EXT) data line. The keycode is then used as a new address for the active ROM.

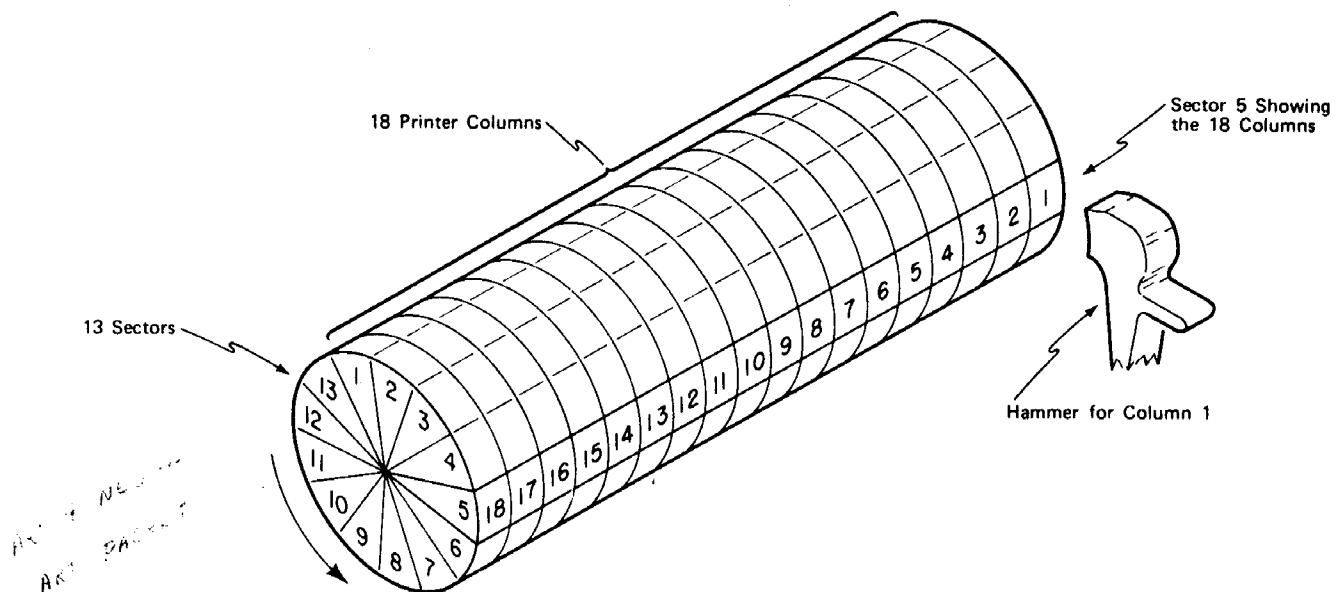

Figure 2-4. The SEIKO Print-drum

#### Data Storage Circuits

Each of the three MOS data storage units (ICs) contain ten, 56-bit shift registers. These circuits communicate with the A&R over the bidirectional BCD line; the storage circuits are addressed on the BCD line, they then transmit the data, in the designated register, to the A&R on the same line.

Each data storage unit has six pins which are hardwired on the circuit board to provide an individual address for that unit. Only the unit which has been correctly addressed on the BCD line will output the data from the register designated by the second part of the address.

Timing for the data storage assembly is provided by the START signal from the A&R.

#### 9805A Optional Data Storage Board

Addresses are provided for the ROMs on the data storage board by the C&T via the processor. The data storage ROMs, in turn, provide the instructions and word-select signals to enable the use of the data in the storage registers.

Timing for the data storage ROMs is provided by the system clock signals and SYNC.

#### 9805A Optional Plotter Interface

The eight I/O lines (C1 through C8) and four of the processor data-output lines (C10 through C13) are buffered on the interface and are then used as data inputs for the plotter. The control signals used to transfer the data to the plotter are decoded outputs of the processor, which, itself, is receiving instructions from the interface ROMs. Control is transferred to these ROMs by instructions from the main system ROMs which instruct the processor to issue a group I/O enable signal (GIOE), thus activating the interface's ROMs.

## CHAPTER 2

### GENERAL PRINCIPLES OF OPERATION

#### 9805A Statistics Keyblock

The statistic keyblock keys are electronically overlayed on the main keyboard keys, and thus are scanned synchronously with those keys. When a stat-block key is pressed, however, an additional signal, FUNCTION BLOCK SELECT (FBS) is generated which sets the FLAG' signal. The processor sequentially sets the FLAG signal which, in turn, sets status-bit 11 in the C&T. An ensuing system ROM instruction tests status-bit 11. When status-bit 11 is set, other instructions are issued which instruct the processor to:

- disable instructions to the A&R and C&T from the main system ROMs.
- output a SELECT ROM-GROUP B (SRB) signal, thereby enabling the C&T address outputs (Ia) to the keyblock ROMs.

Thus, the C&T, A&R, and processor all begin operating using the keyblock ROM instructions.

#### Display and Drivers

The display chip is a magnified five-digit cluster. Each digit has a spherical lens molded in the plastic cover.

The LED's are more efficient if they are pulsed at a low duty cycle rather than driven by a dc source. In this display, energy is stored in inductors then 'dumped' into the light-emitting diodes. This drive technique allows a high degree of multiplexing; the digits are scanned one at a time, one segment at a time.

The anode driver generates the two-phase system clock and the segment (anode) drive-signals, decodes the data from A&R, inserts the decimal point, and sends shift signals to the other axis of the multiplex circuitry (i.e., the cathode driver). The cathode driver contains a 15-position shift register which is incremented for each digit position while the anode driver is scanning that digit. The entire 15-digit display is scanned once each word-time and is then reset to begin by the START signal from the A&R circuit.

#### The Model 81 Buffered Keyboard

The Model 81 Opt. 003 Display and Opt. 002 Father boards contain a 9x64-bit random-access buffer. This buffer receives the key-down (KD) inputs from the keyboard together with the C&T's KS outputs and, when the calculator is not busy, sends the key-down (KD) information, in the same order in which they originally occurred (i.e., first in, first out), to the C&T. The circuit uses the IOC1-IOC3 and SCE signals to determine when the calculator is busy.

The 9 bits of data stored for each of the 64 keys are 5 KD signals, 3 encoded KS signals, and KS0. When the calculator is ready to accept a key input, the encoded KS bits together with KS0, are compared to the C&T KS bits to ensure that the keycode is output to the C&T only during the correct calculator bit-times. When the current KS outputs are identical to the KS outputs when the key was pressed, the previously stored KD data is input to the C&T.

Key bounce is eliminated by a 10 msec one-shot which is triggered by a key-down detector. Other circuits are required to ensure that the buffer does not interfere with other C&T operations and to permit the use of either a MOSTEK or an AMI C&T.

## CHAPTER 3 MODELS 46 AND 81 THEORY OF OPERATION

### INTRODUCTION

The information contained in this chapter describes the Model 46 and Model 81 Calculator 'system' operation rather than the operation of each individual circuit. Information contained in Chapter 2 briefly describes the individual circuits; you must have a thorough understanding of that information before continuing with this chapter. Chapter 4 provides the theory of operation for 9805A Calculators.

Figure 3-6 is a block diagram of the Model 46 and Model 81 Calculator system and shows the signals used in the system, their originating device, and destination. That information will be useful during the remainder of the chapter.

### LOGIC DESCRIPTION

The logic levels used in the Model 46 and Model 81 Calculator systems are  $\emptyset$ V and +6V, except for the clock driver outputs which are +6V (logical  $\emptyset$ ) or -12V (logical 1).

Both negative- and positive-true logic is used in the system. Negative-true logic signals are shown as the signal name or mnemonic with a bar across the top of the characters; these signals are a logical 1 at  $\emptyset$ V levels. Positive-true logic signals do not have the bar across the top of the characters; these signals are +6V when true.

Table 3-1 lists the mnemonics and the associated signal names which are used in the Model 46 and Model 81 Calculator systems.

Table 3-1. The System Signal Mnemonics

MNEMONIC	NAME	FUNCTION
ADV	Advance	paper advance signal to the printer
BCD	Binary-coded-decimal	BCD input/output line to A&R from all data storage circuits and the I/O processor
C1 thru C20	Data C1 thru Data C20	I/O processor data outputs to the printer electromagnets via the drivers
Col 1 thru Col 18	Column 1 thru Column 18	printer electromagnet-driver outputs to enable hammers
CRY	Carry	carry information to the C&T from the A&R
Data A thru Data E	Data A thru Data E	Encoded display information from A&R to display circuits
EIS1	Enable Instruction Set 1	signal from I/O processor used to enable instructions from the ROMs to the A&R and C&T
EXT	External data	data input line from the I/O processor to the C&T
FLG'	Flag Prime	this signal is an input to the I/O processor when a keyboard key is pressed which affects all subsequent operation (e.g., PRINT OFF)
FLG	Flag	a processor output to the C&T which is set by the processor FLG' input

**CHAPTER 3**  
**MODELS 46 AND 81 THEORY OF OPERATION**

**Table 3-1. The System Signal Mnemonics (Cont'd)**

MNEMONIC	NAME	FUNCTION
la	Instruction Address	an eight-bit input to the ROMs which contains the ROM-address information from the C&T
IOC1-3	Input/Output codes, bits 1 thru 3	processor outputs used as 'system busy' indicators
ls	Instruction	ROM pre-programmed outputs
ls1	Instruction Set 1	instructions which are input to the processor, C&T, and A&R
KD	Key-down	signal from keyboard to C&T indicating a key is down (LSD of la)
KS	Key-select	signals to the keyboard from the C&T (MSD of la)
DECIMAL	Manual Decimal Point	Model 81 signal used to indicate the position of the DECIMAL/AUTO· key
PWO	Power-on	logic signal used to preset the system when power is switched ON
Φ1	Phase 1	first phase of the 2-phase clock signal (170 KHz)
Φ2	Phase 2	second phase of the 2-phase clock signal
RED	Red Ribbon	red ribbon select signal which enables the appropriate printer solenoid
RESET	Reset	print-drum row 0 indicator, used to generate TR signal
SCE	Select Code Enable	strobe pulse used to enable coded I/O bits (IOC1-IOC3)
SRT	Start	word-time bit-0 indicator from A&R
SYNC	SYNC	word synchronization signal
TP/TL	Printer timing	print-drum row timing indicator, used to generate TP
TP	Printer timing/time clocked	printer timing pulse which is phase locked to system. Used to increment row counter in the processor
TR	Timing reset	a processor input from the printer used to reset the hexadecimal counter to 0
WS	Word Select	signal from either a ROM or the C&T used to enable the portion of a word to be operated on by the A&R

## SYSTEM POWER-UP

Of the four power supplies (+6V, +10V, +15V, and -12V) the +6V supply powers-up first to ensure that the system clock is operating before the MOS/LSI logic. The +10V supply, which generates the +7.5V and +3.75V supplies, is used by the display circuits. The +15V supply is used only by the printer. The +6V and -12V supplies provide power for the MOS circuits.

### NOTE

The CMOS logic in the Model 46 and the Model 81 use +6V for power.

### Generating PWO (Power-On)

When the C&T receives power, the two-phase system-clock inputs from the Father Board or, if installed, the Display Board cause the circuit to begin sequencing and, subsequently, the first SYNC signal is generated. The SYNC signal clocks flip-flop U18B, which generates the signal PWO. While PWO is 0 volts, the SYNC signal, together with  $\Phi_1$  and  $\Phi_2$ , are synchronizing the system.

The PWO signal is used to:

- set the logic to a predetermined state before system operation begins.
- delay any system operations for at least 500 msec to allow time for the print-drum to obtain its normal operating speed.
- preset the ROMs; only ROM 0 of group A is activated and can output instructions when PWO is released.
- preset the I/O processor to Enable Instruction-Set One (EIS1), thereby ensuring the instruction outputs of the ROMs are input to the A&R and C&T.
- hold the C&T's la (address) outputs at logical 0; the C&T attempts to output incremented addresses each word time, but the la line is held at a logical 0 by the PWO signal.

Before PWO is released, the system is fully synchronized and the print-drum is rotating at its normal operating speed. Thus, when PWO is forced to +6V by the first SYNC signal after the 'D' input of U18B is high, the system can begin processing data.

### The Power-Up Routine

Since address zero is present on the la line and ROM 0 of group A is selected, the instruction in address 0, of ROM 0 in group A, is the first instruction executed by the system. Together with the ensuing instructions, this instruction preconditions the system for subsequent, user-initiated operations. The preconditioning, or power-up, routine determines the display format, the information in the display (zeros), and it causes CLEAR to be printed. The final instruction in the routine branches the system to a set of instructions which are used as a 'display-wait loop'.

While the power-up routine is being executed, the calculator ignores any key which is down. The power-up instructions do, however, interrogate the status of the PRINT OFF key. Once the status of the PRINT OFF key has been tested, the system assumes that it will not be changed until after the print instructions have been completely executed. If the PRINT OFF key is pressed during any printing routine, power to the printer is removed, thereby removing the timing signals to the I/O processor circuit. Thus, the processor is disabled sometime during the print cycle (e.g., while the processor is being prepared to print CLEAR), which may 'hang-up' the system or result in otherwise unexpected operations.

## THE DISPLAY-WAIT LOOP

When the power-up instructions have been completed — *or any other time the system is idle* —, the system exits to a set of ROM instructions, called the display-wait loop, during which the system continually searches for a 'key-down' condition. Until a key-down occurs, information in the A&R circuit is continuously recirculated and displayed while the remainder of the system is idle. When a key, other than the DECIMAL key or the PRINT OFF key, is pressed, a status bit (0) in the C&T is set and the octal equivalent-code for that key is loaded into the C&T's buffer register. Then, the wait loop instructions are exited and a set of 'key-down preparation routine' instructions are accessed.

The DECIMAL and PRINT OFF keys do not affect the wait loop. These keys are tested each time a data entry or printing operation is begun.

## CHAPTER 3 MODELS 46 AND 81 THEORY OF OPERATION

## GENERATING KEYCODES

The keyboards are electronically constructed as a 5X8 matrix of switches. When a key is pressed, it connects one of eight key-select lines (KS) to one of the five key-down lines (KD) (see Figure 3-1).

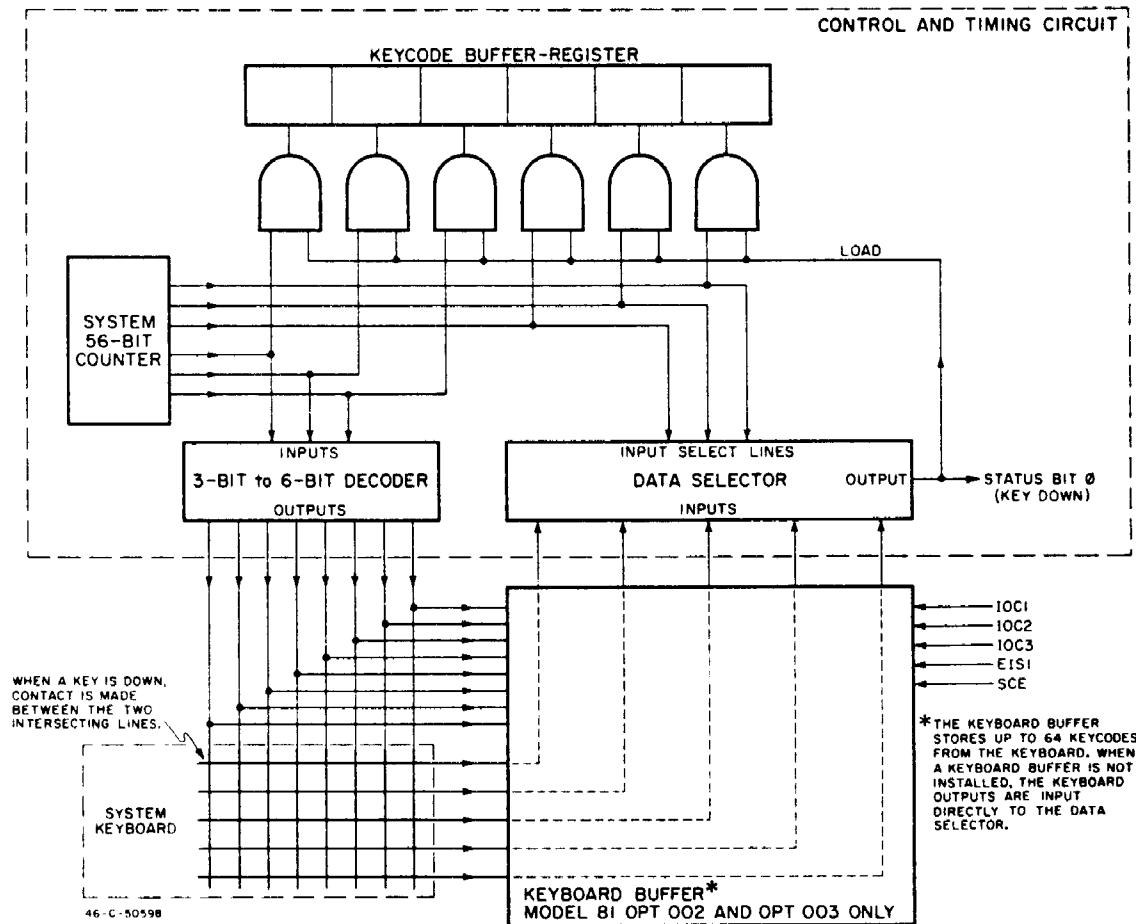

## NOTE

Model 81 Calculators with either Option 2 or Option 3 installed contain a keyboard buffer and operate somewhat differently; see 'THE MODEL 81 BUFFERED KEYBOARD' at the end of this chapter.

The eight KS lines are sequentially driven by a 3-bit to 8-bit decoder in the C&T; the decoder inputs are the three significant bits (LSB) of the C&T's 56-bit counter. Thus, each KS line is driven once each eight bits of the system 56 word (i.e., 7 times each word). When a key is down, the pulses on the KS line corresponding to that key are coupled to the associated KD line, then input to a data selector in the C&T.

The data selector uses the three most significant bits of the 56-bit counter to sequentially select each KD line; each line is selected once each word time. When the KD line being selected is pulsed by the decoder, via the associated KS line, the data selector transfers the input signal to its output. This signal is then used to load the keycode-buffer register with six outputs of the 56-bit counter; 16 states of the counter are not used. The output of the data selector is also used to set status-bit 0, the key-down status bit, in the C&T. Status-bit 0 must be reset — that is, the key must be released before subsequent keys are accepted.

The keycode-buffer register is loaded with the same octal keycode once each word-time until the key is released. keycode in the buffer register is, however, not loaded into the address register until the C&T receives a ROM instruc to do so; the instruction for that operation is contained in the 'key-down preparation routine' instructions (desc next).

**Figure 3-1. The Keyboard Scanner**

### KEY-DOWN PREPARATION ROUTINE

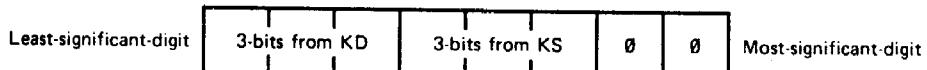

When a keyboard key, other than DECIMAL or PRINT OFF, is pressed, a keycode corresponding to that key is generated (see 'Generating Keycodes') and status bit 0 is set. The ROM instructions in the display-wait loop continually test status bit 0 to determine if a key has been pressed. When status bit 0 is set, the system exits the wait loop and enters the key-down preparation routine. The primary functions of this routine are:

- to provide a software-controlled delay to ensure the key entry was not due to keybounce.
- to blank the display.
- to prepare the A&R, C&T, and the I/O processor to perform any instruction required to service the key which is down.
- to test a status-bit which is set by the SHIFT key. If that bit is set, an instruction is issued to activate a particular ROM. If the bit is reset, another instruction activates a different ROM. The ROM activated by this process contains the first instruction for servicing the keycode in the keycode-buffer register. (ROM selection is described later in this chapter.)

Upon completion of the preparation routine — which may require up to 60 word times — the calculator system is ready to service the keycode in the user-defined display mode of operation.

### SERVICING THE KEYBOARD INPUTS

The final instruction in the preparation routine loads the keycode from the C&T's buffer register into the address register. Two bits are added to the six-bit keycode by hardware in the C&T to make the eight-bit instruction address (Ia). Both bits are zeros and are placed in the two most significant bit positions. The eight-bit address, in the address register, is in the form:

The C&T outputs the address (Ia) from the address register to the ROMs during bit-times 19 through 26 of the ensuing word (i.e., the first word after the completion of the preparation routine). This address is stored in the address register of all ROMs in the system. Each ROM decodes the address and, at bit-time 44, the instruction specified by the address is loaded, in parallel, into each ROM's instruction register. Only the active ROM — that is, the ROM which was selected during the preparation routine — can, at this time, output the instruction (Is) from the instruction register.

### A SUMMARY OF THE PRECEDING INFORMATION

Before continuing, let's briefly summarize the operations which have previously taken place.

- Initially, the calculator was OFF. When the unit was switched ON, the system began synchronizing and PWO was generated to preset the system and to delay subsequent operations until the printer was ready.
- Next, a routine was entered that set up the correct display and printed CLEAR (unless the PRINT OFF key was down).
- The calculator then entered a wait loop. During this time, the display was on and a continual test for a key-down condition was taking place.
- When a key was pressed, the calculator exited the wait loop and began a keydown preparation routine during which the system was prepared to accept the 6-bit keycode stored in the C&T. The last instruction in the routine activated the correct ROM and loaded the keycode into the C&T's address register; while loading the keycode into the address register, two zeros were added to complete the 8-bit address.
- Finally, after completion of the preparation routine, the keycode was loaded into each ROM's address (Ia) register and, at bit-time 44, the instruction in the specified address was loaded into each ROM's ten-bit instruction register.

Until this time, the operations performed by the calculator have been reasonably well defined. From this time on, however, the instructions define the operations performed by the calculator; each instruction differs from each other instruction, depending upon the requirements of the problem being solved.

## CHAPTER 3 MODELS 46 AND 81 THEORY OF OPERATION

### THE ROM INSTRUCTIONS

#### A Word About the First Keycode-Instruction

Let's discuss the instruction, just loaded into the instruction register, for a moment.

Since only 5 key-down and 8 key-select lines are used, only 40 (8X5) instructions can be accessed by keycodes the keyboard. All of those instructions are clustered within one ROM (one ROM is active for shifted keys, and for unshifted keys). All keycodes, however, require more than a single instruction to perform the required operation. Therefore, each keycode eventually addresses a ROM-select or branch instruction to actually access the routine service that key. Some of those routines may contain additional branch or jump-subroutine instructions to complete servicing the key.

#### The Instruction

Each ROM contains 256 ( $2^8$ ) instructions (Is), each of which is accessed by a different instruction address (Ia), and only one instruction is output, bit-serially, during bit-times 45 through 54 of each word. Those instructions:

- are decoded by the issuing (active) ROM and, if the operation is arithmetic, 3-bits of Is determine which of the 6 possible WS signals is output to the A&R during the ensuing word-time. (Two types of WS signals originate in the C&T during arithmetic operations).
- are decoded by the inactive ROMs to provide an arrangement whereby control can be switched from one to another. Only one ROM in the system is active (i.e., outputting instructions) at one time. The address of the ROM-select instruction is incremented in the C&T, then used as the selected ROM's instruction address (Ia).
- are decoded by the C&T, thereby providing control of the C&T operations and also providing branch subroutine instruction addresses for the system. (The return address of subroutine operations is the incremented address of the subroutine instruction. It is stored in the C&T until it is required for the return.)

Other instructions are decoded by the C&T word-select outputs. This occurs only during certain arithmetic operations performed by the A&R circuit. The C&T word-select signals either specify a single digit operation or an operation on all digits less than a specified digit number; WS from the C&T can never specify operation of the center portion of a word.

- control of the A&R. Data is placed in the A&R registers either by arithmetic operations or by exchanging between registers. BCD data can be input or output to the A&R by additional instructions.

The BCD data in each of the seven A&R registers can be exchanged or transferred using other instructions. Arithmetic operations in the calculator are accomplished in the A&R by arithmetic instructions. These instructions, and only these instructions, require a WS input signal during the ensuing word-time.

- toggle the display information to the display circuits. Yet another instruction must be used to disable information to the display.
- control the I/O processor which, in turn, controls the printer and the 'Busy' light.

### THE I/O PROCESSOR CIRCUIT

When a printout is necessary, instructions are used to load the row (or sector) hexadecimal number of the desired character into selected digit positions in two 56-bit registers; each digit position corresponds to one column on the print-drum. (One of the two 56-bit registers is located in the A&R circuit.) When the ROM-generated hexadecimal number in each digit-position corresponds to the hexadecimal print-drum row number, the hammer in the corresponding column is activated.

The I/O processor always 'listens' to the instructions on the Is bus. Some instructions, however, are ignored by the processor while others instruct the processor to disable instructions to the A&R and C&T circuits.

When the system is busy performing an operation, two processor outputs, SCE and IOC3 are used to switch the Busy Light on (SBL).

Finally, the status of the DECIMAL and PRINT OFF keys are tested and the results recorded in the A&R and C&T by the processor. The processor receives an instruction to test one of those keys, then outputs an enable signal which, if the key is down, forces the FLG' line to a logical 1. The resulting logical 1 FLG signal then sets status-bit 1 in the C&T, thereby causing a ROM instruction to be issued that performs the appropriate operation. (The PRINT OFF key, when pressed, also removes power to the printer.)

## THE DISPLAY CIRCUITS

### The System Clock

One of the functions of the anode driver circuit is to provide the two-phase clock pulses shown in Figure 3-2. With the exception of two externally-connected timing components, the anode driver contains all of the circuits necessary to perform this function. Systems which do not contain the anode driver utilize discrete components for the clock circuit; these components are located on the Father Board (A4). The two-phase clock frequency is 170 KHz.

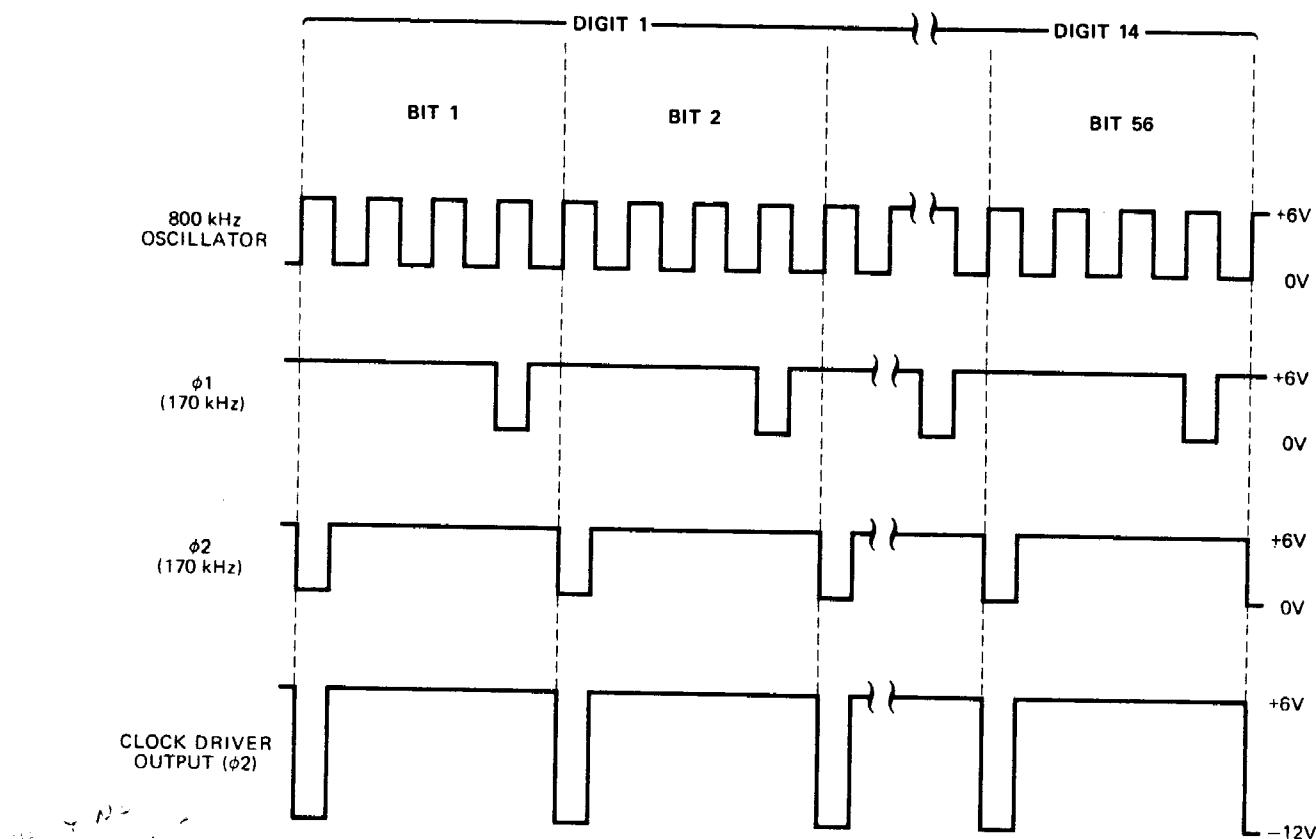

Figure 3-2. System Two-phase Clock Signals

### The Anode and Cathode Drivers

The multiplexed Data A through Data E information, which is output by the A&R, is input to the anode driver. The anode driver demultiplexes the information and drives the anode of the appropriate display LEDs; each LED is one segment of a digit (see Figure 3-3). The anode driver provides drive for the same segments in each of the 15 display digit positions. The cathode driver, however, selects a single digit position for displaying the information.

When the anode driver has completed the display of a digit (i.e., after four system bit-times), it outputs a shift-clock pulse to the cathode driver. The cathode driver then enables the next digit (to the left) for displaying the ensuing A&R Data A through Data E outputs. Two consecutive shift-clock signals are output during any digit which is followed by a decimal point; the decimal-point data is output by the A&R at the same time as the preceding digit-data. This results in a 15-digit display with only 14 digits in the system-word. Digits which are blank are treated the same as other display digits, except when the anode driver decodes the A&R circuit outputs, no LED anodes are driven.

The START signal from the A&R circuit resets the cathode driver's digit counter, thereby setting the cathode driver to digit-position one.

The 'Busy Light' is switched on or off by the I/O processor circuit using instructions from one of the ROMs.

## CHAPTER 3 MODELS 46 AND 81 THEORY OF OPERATION

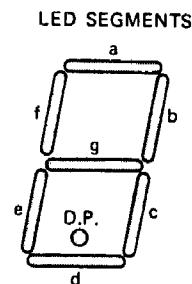

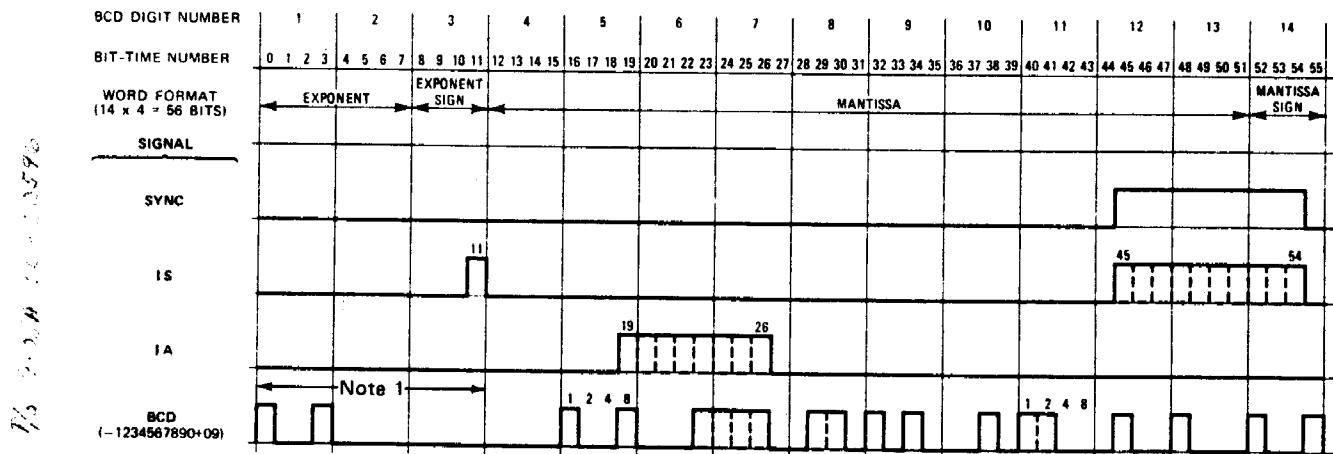

Figure 3-3. The Segments of Each Display Digit

### THE A&R BCD OUTPUTS

The only method of 'looking' at information in the system is to use an oscilloscope, synchronized to either STA (bit 0), or the trailing edge of SYNC (i.e., bit 54), to monitor the BCD line on the A&R. Since the BCD data in A&R is recirculated once each word-time when the calculator is not busy, that data can be seen on the BCD out Figure 3-4 shows an example of data on the BCD line when the display is:

-1.234567890 09

Note again that negative exponents are handled by the A&R in the ten's-complement notation.

NOTE 1: When a negative exponent occurs, the system handles the exponent in the ten's-complement notation (see Figure 2-1 in Chapter 2).

Figure 3-4. Looking at the BCD Information

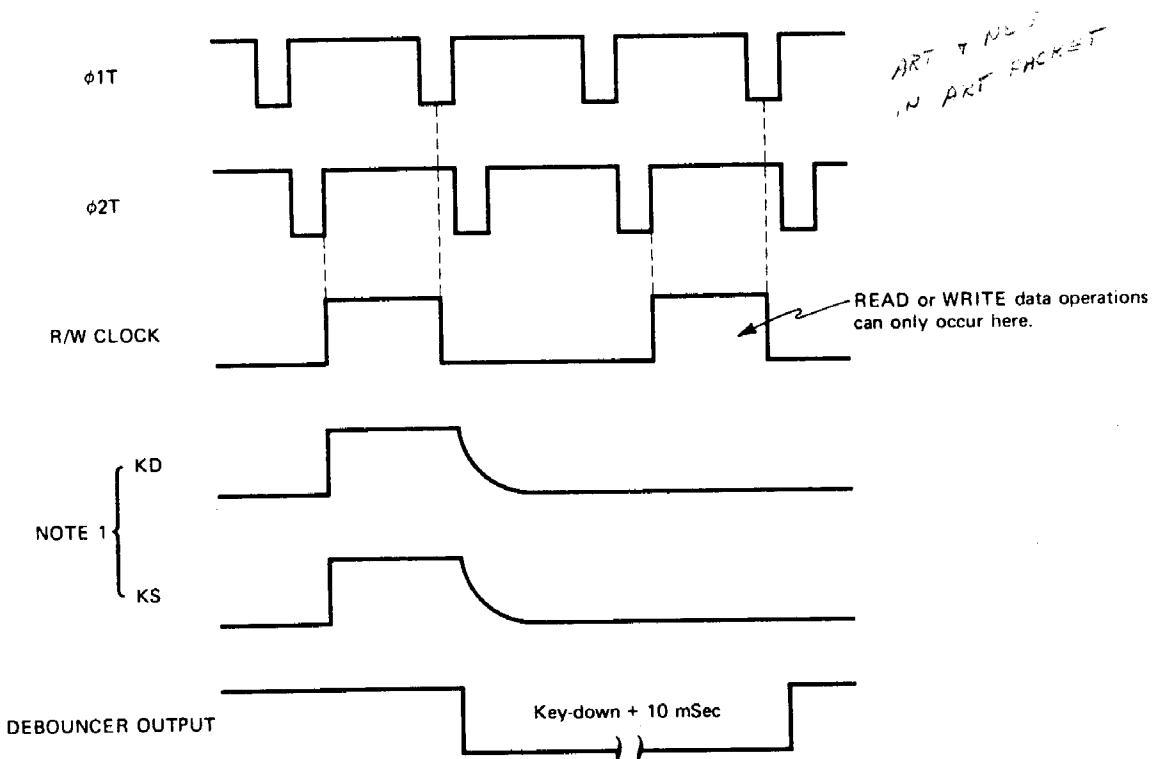

### THE MODEL 81 BUFFERED KEYBOARD

The buffered keyboard circuits, located on both the Opt 3 Display and the Opt 2 Father Boards, interrupt the KD signals between the keyboard and the C&T and, at the same time, monitor the C&T's KS outputs (see Figure 3-1).

When a key is down, a 10 msec one-shot is triggered to protect against keybounce. Then, the keyboard's KD signals, together with encoded KS signals from the C&T, are stored in one address of a 9X64-bit, random-access memory (RAM). Up to 64 encoded keycodes can be stored in the buffer.

The data in the buffer is output only when two conditions are met. First, the calculator must *not* be busy processing any previous inputs, as indicated by the states of the IOC1, IOC2, IOC3, EIS1, and SCE data. Second, the C&T's KS outputs, when encoded by the buffer circuits, must be identical to the KS data stored in the RAM. When those conditions are met the calculator is ready to accept the KD data from the buffer and the KS data for the keycode (i.e., the system bit-time) is correct. The KD information first input to the buffer is then output to the C&T. This process continues, with the buffer sequentially outputting KD information on a first in-first out basis, until the RAM is empty.

To implement the use of the keyboard buffer, R/W Clock, R/W Control, Key-down Detector, Debouncer, KS Encoder, and KS Comparitor circuits are used. All of these circuits, together with the RAM, are contained on either the Father Board or Display Board, whichever is installed. Figure 3-5 is a timing diagram of the buffer circuits.

NOTE 1: The actual KD & KS signals seen depend upon whether a MOSTEK or AMI C & T is being used. In either case, the signals are NOT precisely as represented here.

Figure 3-5. The Keyboard Buffer Timing

## INTRODUCTION

The information contained in this chapter describes the 9805A Calculator 'system' operation rather than the operation of each individual circuit. Information contained in Chapter 2 briefly describes the individual circuits; you should have a thorough understanding of that information before continuing with this chapter. The Models 46 and 81 Theory of Operation is contained in Chapter 3.

If you are already familiar with the information in Chapter 3 only those sections which are preceded by a ■ symbol need be read. Those sections contain information, usually shown in italics, which differs from the information in Chapter 3.

Figure 4-5 is a block diagram of the 9805A calculator system and shows the signals used in the system, their originating device, and destination. That information will be useful during the remainder of the chapter.

## ■LOGIC DESCRIPTION

*The logic in the 9805A system requires that both MOS and bipolar logic levels be used; bipolar logic levels are 0V or +5V, whereas MOS-circuit logic levels are 0V or +6V. The clock driver outputs are +6V and -12V.*

Both negative- and positive-true logic is used in the system. Negative-true logic signals are shown as the signal name or mnemonic with a bar across the top of the characters; these signals are a logical 1 at 0V levels. Positive-true logic signals do not have a bar across the top of the characters; *these signals are either +5V or +6V, depending on the type of logic circuits in use, when true.*

*Table 4-1 lists the mnemonics and the associated signal names which are used in the 9805A system.*

Table 4-1. The 9805A System Signal Mnemonics

MNEMONIC	NAME	FUNCTION
AUTO•	Automatic Decimal	AUTO• key down
$\bar{A}$	Not A	disable Is and WS from the mainframe ROMs to the A&R and C&T
ADV	Advance	paper advance signal to the printer (C19•C20)
$\bar{B}$	Not B	disable Ia to ROM group B
BCD	Binary-coded-decimal	BCD input/output line to A&R from all data storage circuits and the I/O processor
BDE	Binary Data Enable	enable signal for the BCD data from the system data storage circuits
$\bar{C}$	Not C	disable Ia to ROM group C
C1 thru C20	Data C1 thru Data C20	I/O processor data outputs to both the plotter I/O and printer electromagnets via the drivers. C1 through C8 are inputs from PROM
Col 1 thru Col 18	Column 1 thru Column 18	printer electromagnet-driver outputs to enable hammers

**Table 4-1. The 9805A System Signal Mnemonics (Cont'd)**

MNEMONIC	NAME	FUNCTION
CRY	Carry	carry information to the C&T from the A&R
Data A thru Data E	Data A thru Data E	encoded display information from A&R to display circuits
DBL	Disable	see $\bar{A}$
EIS1	Enable Instruction Set 1	signal from I/O processor used to enable instruction from the ROMs to the A&R and C&T
EXT	External Data	keycodes being input from the I/O processor to the C&T. These keycodes originate in the PROM
FBS	Function Block Select	signal generated on mother board which indicates that a Stat block key is down. Used to force the processor $FLG'$ low
FLG'	Flag Prime	this signal is an input to the I/O processor when a keyboard key is pressed which affects all subsequent operations (e.g., PRINT OFF). FBS, the function-block select signal, also generates a $FLG'$ input signal
GIOE	Group I/O Enable	I/O processor decoded output which enables the plotter interface
Ia	Instruction Address	an eight-bit input to the ROMs which contains the ROM-address select information
IOC1-3	I/O Codes, bits 1 thru 3	Coded I/O control information
Is	Instruction	ROM pre-programmed outputs
IsB	Instruction Set Buffered	Is signals which are buffered
Is1	Instruction Set 1	instructions which are input to the processor, C&T, and A&R
Is2	Instruction Set 2	instructions which are input only to the processor

Table 4-1. The 9805A System Signal Mnemonics (Cont'd)

MNEMONIC	NAME	FUNCTION
KD	Key-down	input line to C&T on which a signal is returned when a key is down
KS	Key-select	output of C&T to the keyboard
MPWO	MOS Power-on	MOS power-on-preset signal; MPWO is 0V at turn-on
PWO	Power-on	bipolar logic signal used to preset the logic when power is switched ON
$\Phi 1$	Phase 1	first phase of the 2-phase clock signal (170 KHz)
$\Phi 2$	Phase 2	second phase of the 2-phase clock signal
READ	Read	I/O processor decoded output to PROM which enables the PROM keycode outputs
RED	Red Ribbon	red ribbon select signal which enables printer solenoid; generated by the combination of C19 with C20
RESET	Reset	print-drum row 0 indicator, generates the TR signal
RGC	ROM Group Clear	clears any previously selected ROM group enable signals
SBL	Set Busy Light	Busy-light ON signal
SCE	Select-Code Enable	strobe pulse used to enable I/O control data (IOC1-IOC3)
SRA	Select ROM Group A	I/O processor output used to reset the $\bar{A}$ signal
SRB	Select ROM Group B	processor output signal which generates SRB <sub>1</sub> when a keyblock is installed

MNEMONIC	NAME	FUNCTION
SRC	Select ROM Group C	processor output signal which generates SRC <sub>1</sub> when the data storage assembly is installed
SRB <sub>1</sub>	ROM Group B Present	signal which resets $\bar{B}$ when keyblock is installed
SRC <sub>1</sub>	ROM Group C Present	signal which resets $\bar{C}$ when data storage assembly is installed
SRT	Start	word-time bit-0 indicator from A&R
SRTB	Start, Buffered	buffered SRT signal
SYNB	SYNC B	buffered word synchronization signal
TP/TL	Printer Timing	print-drum row timing indicator, used to generate the TP signal
TP	Printer timing/time clocked	printer timing pulse which is phase locked to system used to increment row counter in processor
TR	Timing Reset	print-drum row 0 indicator, used to reset the processor row counter to 0
WS	Word Select	signal from either a ROM or the C&T used to enable the portion of a word on which the A&R is to operate
WSB	Word Select Buffered	buffered WS signal output
YINTF	Interrogate Flag	decoded processor output, used to determine if the plotter interface is ready

## SYSTEM POWER-UP

■ Of the five power supplies (+5V, +6V, +10V, +15V, and -12V) the +5V supply powers-up first. Thus, the system clock is operating before the MOS/LSI logic. The +10V supply generates both the +7.5 and +3.75V supplies which are used by the display circuits. The +15V supply is used only by the printer. The +6V and -12V supplies provide power for the MOS circuits.

### ■ Generating PWO (Power-ON)

When the C&T receives power, the two-phase system clock inputs from the Father Board or, if installed, the Display Board cause the circuit to begin sequencing and, subsequently, the first *SYNB* signal is generated. (Note that before the *SYNB* signal is generated, the C&T may attempt to output an *la*; this address is all zeros due to the address register having been cleared when power was removed.) The *SYNB* signal clocks *flip-flop U23A*, which generates the signal *PWO*. *MPWO*, the *MOS logic-level equivalent of PWO*, is generated by the *PWO* signal. While *PWO* is 0 volts, the *SYNB* signal, together with  $\Phi_1$  and  $\Phi_2$ , are synchronizing the system.

The *PWO* and *MPWO* signals are used to:

- set the bipolar logic to a predetermined state before system operation begins.
- delay any system operations for at least 500 msec to allow time for the print-drum to obtain its normal operating speed.
- preset the ROMs; only ROM 0 of Group A is activated and can output instructions when *MPWO* is released.
- preset the I/O processor to Enable Instruction-Set One (EIS1), thereby ensuring the instruction outputs of the ROMs are input to the A&R and C&T.
- hold the C&T's *la* (address) outputs at logical 0; the C&T attempts to output incremented addresses each word time, but the *la* line is held at a logical 0 by the *MPWO* signal.

Before *PWO* is released, the system is fully synchronized and the print-drum is rotating at its normal operating speed. Thus, when *PWO* is reset by the first *SYNB* signal after the 'D' input of *U23A* is high, the system can begin processing data.

### The Power-up Routine

Since address zero is present on the *la* line and ROM 0 of Group A is selected, the instruction in address 0 of Group A, ROM 0 is the first instruction executed by the system. Together with the ensuing instructions, it preconditions the system for subsequent, user-initiated operations. The preconditioning, or power-up, routine determines the display format, the information in the display (zeros), and also causes *CLEAR* to be printed. The final instruction in the routine branches the system to a set of instructions which are used as a 'display-wait loop'.

■ While the power-up routine is being executed, the calculator ignores any key which is down. The power-up instructions do, however, interrogate the status of the mode keys (i.e., *AUTO*• and *PRINT OFF*).

## THE DISPLAY-WAIT LOOP

When the power-up instructions have been completed, or any other time the system is idle, the system begins executing a set of ROM instructions, called the display-wait loop, during which the system continually searches for a key-down condition. Until a key-down occurs, information in the A&R circuit is continuously recirculated and displayed while the remainder of the system is idle. When any key, other than *AUTO*• or *PRINT OFF* is pressed, a status bit in the C&T is set and the octal equivalent code for that key is loaded into the C&T's buffer register. Then, the wait loop instructions are exited and a set of 'key-down preparation routine' instructions is accessed.

The *AUTO*• and *PRINT OFF* keys do not affect the wait loop. These keys are tested each time a data entry or printing operation is begun.

## CHAPTER 4

### 9805A THEORY OF OPERATION

#### GENERATING KEYCODES

- The keyboards are electronically constructed as a 5X7 matrix of switches which, when a key is pressed, connect on the seven key-select lines (KS) to one of the five key-down lines (KD) (see Figure 4-1).

##### NOTE

*The Model 5 does not use key-select line KS-0.*

The seven KS lines are sequentially driven by a 3-bit to 8-bit decoder in the C&T; the decoder inputs are the three least-significant bits of the C&T's 56-bit counter. Thus, each KS line is driven once each eight bits of the system 56 word (i.e., 7 times each word). When a key is down, the pulses on the KS line corresponding to that key are coupled to the associated KD line and input to a data selector in the C&T.

The data selector uses the three most significant bits of the 56-bit counter to sequentially select each KD line; each line is selected once each word time. When the KD line being selected is pulsed by the decoder, via the associated KS line, data selector transfers the input signal to its output. The output signal is then used to load the keycode-buffer register with the six outputs of the 56-bit counter; 21 states of the counter are not used. The output of the data selector is used to set status-bit 0, the keydown status bit, in the C&T.

The keycode-buffer register is loaded with the same octal keycode once each word-time until the key is released. The keycode in the buffer register is, however, not loaded into the address register until the C&T receives a ROM instruction to do so; the instruction for that operation is contained in the 'key-down preparation routine' instructions.

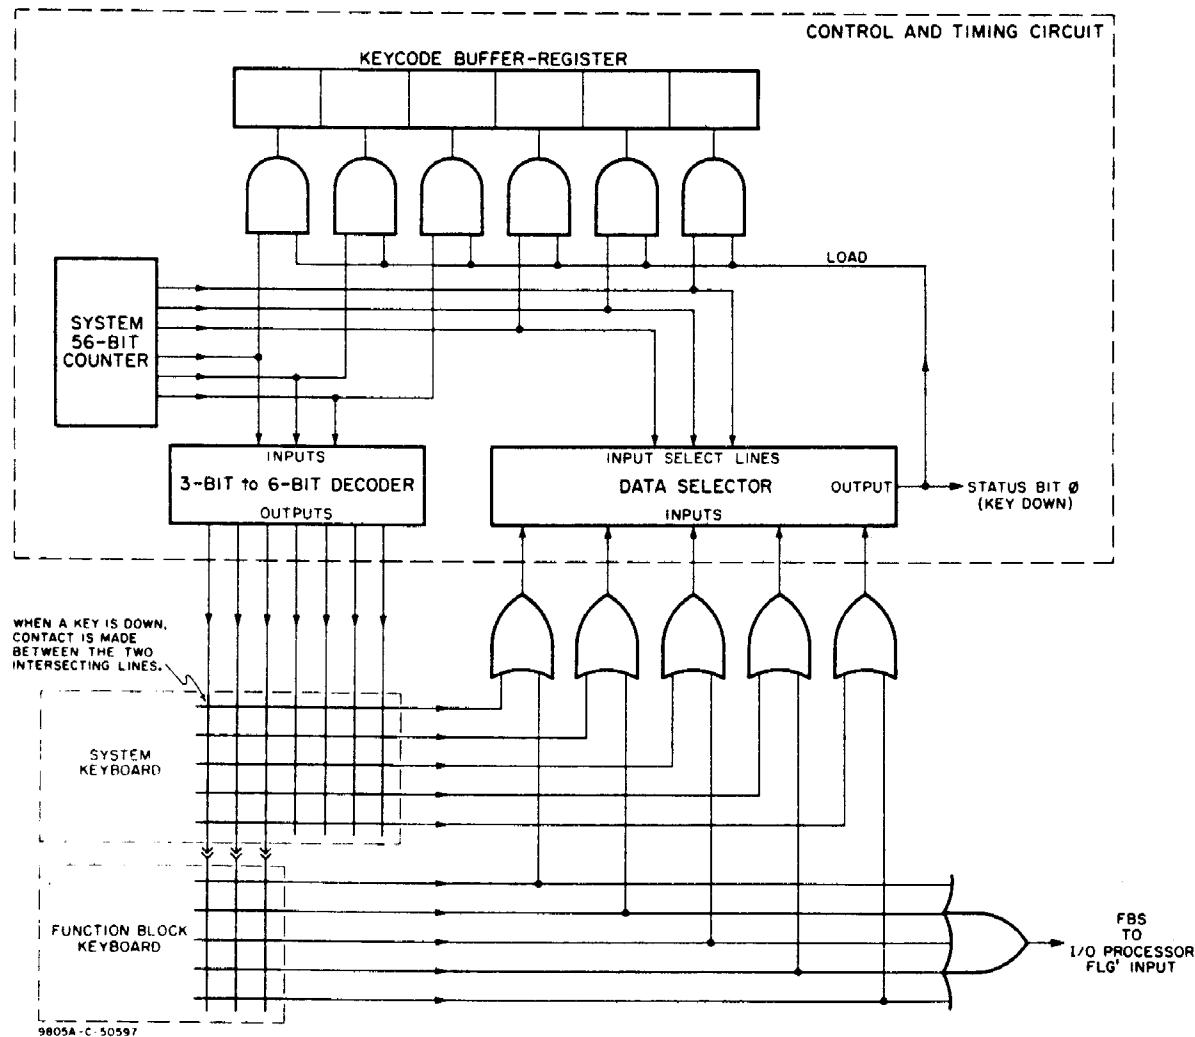

Figure 4-1. The Keyboard Scanner

### KEY-DOWN PREPARATION ROUTINE

When a keyboard key, other than one of the mode keys, is pressed, a keycode corresponding to that key is generated (see 'Generating Keycodes') and status-bit 0 is set; if status-bit 0 is already set, the key is ignored. The ROM instructions in the display-wait loop continually test status-bit 0 to determine if a key has been pressed. When status-bit 0 is set, the system exits the wait loop and enters the key-down preparation routine. The system ignores subsequent key-down conditions until the original key which was down is released. The primary functions of this routine are:

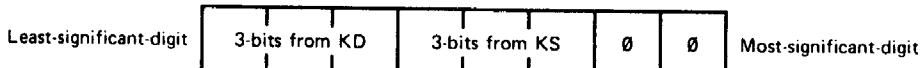

- to provide a software-controlled delay to ensure the key entry was not due to keybounce.
- to blank the display.
- to prepare the A&R, C&T, and the I/O processor to perform any instruction required to service the key which is down.
- to test a status-bit which is set by the SHIFT key. If that bit is set, an instruction is issued to activate a particular ROM. If the bit is reset, another instruction activates a different ROM. The ROM activated by this process contains the first instruction for servicing the keycode in the keycode-buffer register (ROM selection is described later in this chapter).

Upon completion of the preparation routine, which may require up to 20 word times, the calculator system is ready to service the keycode in the user-defined display modes of operation.

### SERVICING THE KEYBOARD INPUTS

The final instruction in the preparation routine loads the keycode from the C&T's buffer register into the address register. Two bits are added to the six-bit keycode by hardware in the C&T to make the eight-bit instruction address (Ia). Both bits are zeros, and are placed in the two most-significant-bit positions. (External keycode entries may not have zeros in the two MSB positions. Those keycodes are described later in this chapter.)

The eight-bit address, in the address register, is in the form:

Beginning at bit-time 56 of the last word in the preparation routine (i.e., approximately 18 words after the key was pressed), the address is clocked, bit-serially, to the ROMs on the Ia bus. The address is received by the ROMs during bit-times 19 through 26 of the ensuing word (i.e., the first word after the completion of the preparation routine). This address is stored in the address register of each ROM in the system. Each ROM decodes the address and, at bit-time 44, the instruction specified by the address is loaded, in parallel, into each ROM's instruction register. Only the active ROM (the ROM which was selected during the preparation routine) can, at this time, output the 10-bit instruction from the instruction register.

### A SUMMARY OF THE PRECEDING INFORMATION

Before continuing, let's briefly summarize the operations which have previously taken place.

- Initially, the calculator was OFF. When the unit was switched ON, the system began synchronizing and PWO was generated to preset the system and to delay subsequent operations until the printer was ready.
- Next, a routine was entered that set up the correct display and printed CLEAR.
- The calculator then entered a wait loop. During this time, the display was on and a continual test for a key-down condition was taking place.
- When a key was pressed, the calculator exited the wait loop and began a keydown preparation routine during which the system was prepared to accept the 6-bit keycode stored in the C&T. The last instruction in the routine activated the correct ROM and loaded the keycode into the C&T's address register; while loading the keycode into the address register, two zeros were added to complete the 8-bit address.
- Finally, after completion of the preparation routine, the keycode was loaded into each ROM's address register and, at bit-time 44, the instruction in the specified address was loaded into each ROM's ten-bit instruction register.

Until this time, the operations performed by the calculator have been reasonably well defined. From this time on, however, the instructions define the operations performed by the calculator; each instruction differs from each other instruction, depending upon the requirements of the problem being solved.

## CHAPTER 4 9805A THEORY OF OPERATION

### THE ROM INSTRUCTIONS

#### A Word About the First Keycode-Instruction

Let's discuss the instruction, just loaded into the instruction register, for a moment.

Since only 5 key-down and 7 key-select lines are used, only 35 (5X7) instructions can be accessed by keycodes from keyboard. All of those instructions are clustered within a single ROM (one ROM is active for shifted keys, another F is active for unshifted keys). All keycodes, however, require more than a single instruction to perform the required operations. Therefore, each keycode eventually addresses a ROM-select or branch instruction which actually access routines to service that key. Some of those routines may contain additional branch or jump-subroutine instruction continue servicing the key.

#### The Instruction

Each ROM contains 256 ( $2^8$ ) instructions (Is), each of which is accessed by a different instruction address (Ia). One only one instruction is output, bit-serially, during bit-times 45 through 54 of each word. Those instructions:

- are decoded by the issuing (active) ROM and, if the operation is arithmetic, 3-bits of Is determine which of six possible WS signals is output to the A&R during the ensuing word-time. (Two types of WS signals originate from the C&T during arithmetic operations.)
- are decoded by the inactive ROMs to provide an arrangement whereby control can be switched from one ROM to another; only one ROM in the system is active (i.e., outputting instructions) at one time. The address of ROM-select instruction is incremented in the C&T, then used as the selected ROM's instruction address (Ia).
- are decoded by the C&T, thereby providing control of the C&T operations and also providing branch subroutine instruction addresses for the system. (The return address of subroutine operations is the incremented address of the subroutine instruction, and is stored in the C&T until it is required for the return.)

Other instructions are decoded by the C&T for the two types of C&T word-select outputs. This occurs during certain arithmetic operations performed by the A&R circuit. The C&T word-select signals either specify a single digit operation, or an operation on all digits less than a specified digit number; WS from the C&T can also specify operations on the center portion of a word.

- control the A&R. Data is placed in the A&R registers either by arithmetic operations or by exchanging data between registers. BCD data can be input or output in the A&R by additional instructions.

The BCD data in each of the seven A&R registers can be exchanged or transferred using other instructions. Arithmetic operations in the calculator are accomplished in the A&R by arithmetic instructions. These instructions and only these instructions, require a WS input signal during the ensuing word-time.

- toggle the display information to the display circuits by another instruction. Yet another instruction must be used to disable the information to the display.
- control the I/O processor circuit, which in turn controls the printer and the external ROM groups (e.g., the plotter interface).

### ■THE PROCESSOR CIRCUIT

When a printout is necessary, instructions are used to load the row (or sector) hexadecimal number of the desired character into digit positions in two 56-bit registers; each digit position corresponds to one column on the print-drum (one of the two 56-bit registers is located in the A&R circuit.) When the ROM-generated hexadecimal number in each digit-position corresponds to the hexadecimal print-drum row number, the hammer in the corresponding column is activated.

The I/O processor always 'listens' to the instructions on the Is bus. Some instructions, however, are ignored by the processor while others instruct the processor to disable instructions to the A&R and C&T circuits (EIS1).

The I/O processor provides control of the optional Model 5 ROM circuits – the plotter interface, data storage circuit, statistics keyblock, and the statistics PROM. When instructions require the use of one of those assemblies, the processor outputs signals, which, when decoded by an external decoder, select the appropriate ROM group (SRA, SRB, or SRC) disabling instructions to the other two groups. Also, instructions are available to interrogate the plotter FLAG signal (YINTF), enable the interface (GIOE), or read information from the PROM (READ). Data is transferred from the I/O processor to the A&R on the BCD line or the C&T on the EXT line.

Finally, the status of the keyboard mode keys, the *AUTO*• and *PRINTER OFF*, is tested and the results recorded in the A&R and C&T by the processor. The processor receives an instruction to test one of those keys, then outputs an enable signal which, if the key is down, forces the *FLG*' line to a logical 1. The logical 1 *FLG*' signal then causes the processor to set status-bit 11 in the C&T (via the *FLG* line), thereby causing a ROM instruction to be issued that performs the appropriate operation.

■The approach described above is also used for keyblock keys. In this case, however, instructions to the C&T and A&R circuits from the keyblock ROMs are enabled and the main system ROM instructions are disabled.

## THE DISPLAY CIRCUITS

### The System Clock

One of the functions of the anode driver circuit is to provide the two-phase clock pulses shown in Figure 4-2. With the exception of two externally-connected timing components, the anode driver contains all of the circuits necessary to perform this function. Systems which do not contain the display option utilize discrete components for the clock circuit; these components are located on the Father Board (A4). The two-phase clock frequency is 170KHz.

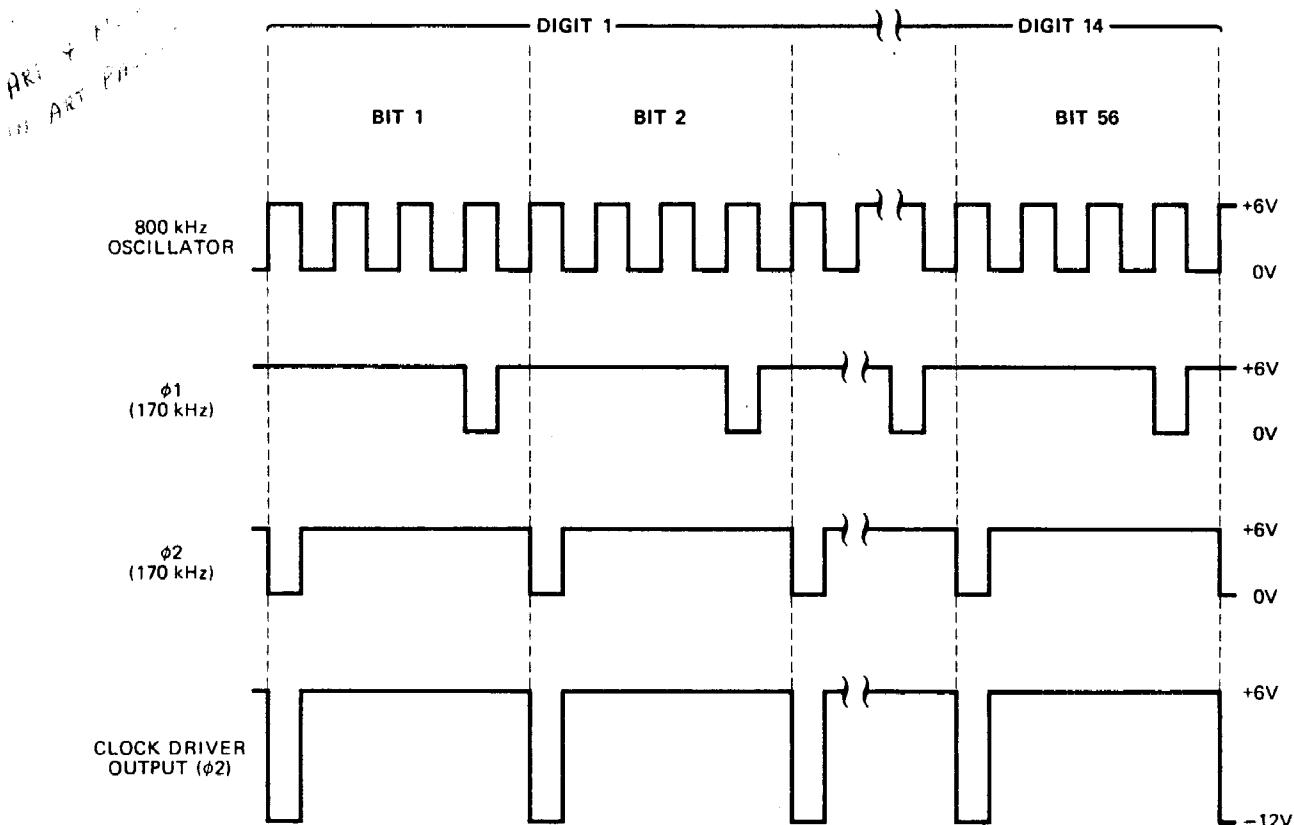

Figure 4-2. System Two-phase Clock Signals

## CHAPTER 4

### 9805A THEORY OF OPERATION

#### The Anode and Cathode Drivers

The multiplexed Data A through Data E information, which is output by the A&R, is input to the anode driver. The anode driver demultiplexes the information and drives the anode of the appropriate display LEDs; each LED is a segment of a digit (see Figure 4-3). The anode driver provides drive for the same segments in each of the 15 positions. The cathode driver, however, selects a single digit position for displaying the information.

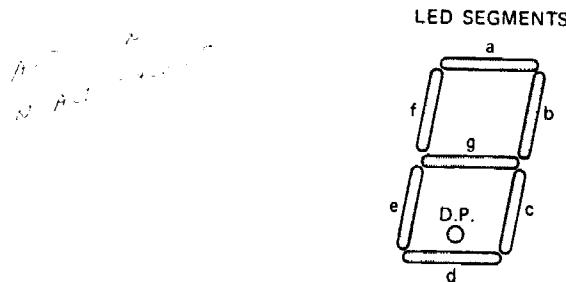

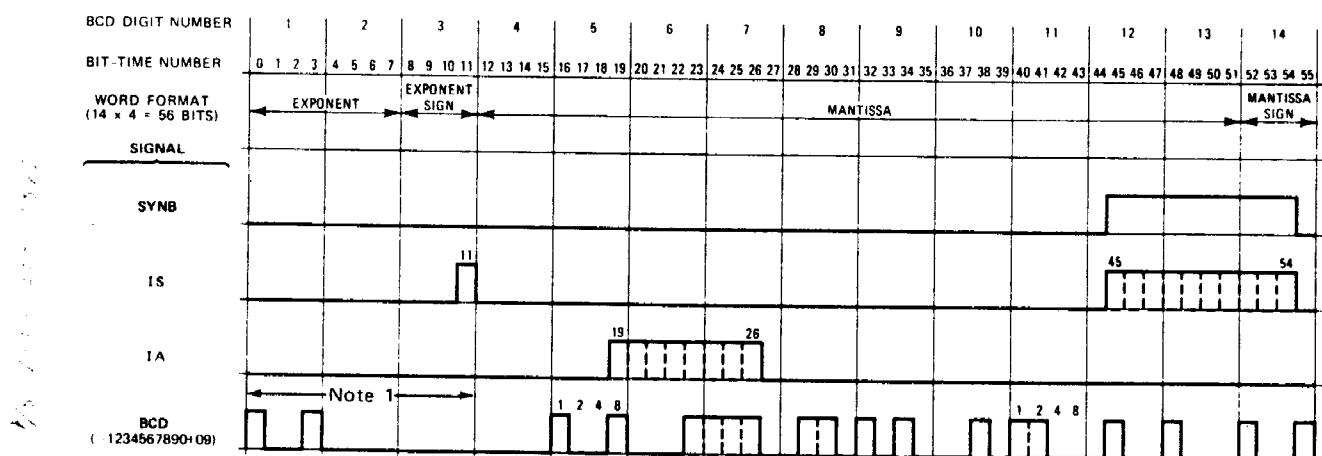

Figure 4-3. The Segments of Each Display Digit

When the anode driver has completed the display of a digit (i.e., after four system bit-times), it outputs a shift-clock pulse to the cathode driver. The cathode driver then enables the next digit (to the right) for displaying the A&R's ensuing Data A through Data E outputs. Two consecutive shift-clock signals are output during any digit which is followed by a decimal point; the decimal-point data is output by the A&R at the same time as the preceding digit-data. Digits which are blank are treated the same as other display digits except that when the anode driver decodes the A&R circuit outputs, no anodes are driven.

The START signal from the A&R circuit resets the cathode driver's digit counter, thereby setting the cathode driver to digit-position one.

The 'Busy Light' is switched on or off by the I/O processor circuit using instructions from one of the ROMs.

Note 1: When a negative exponent occurs, the system handles the exponent in the Ten's-complement notation (see Figure 2-1 in Chapter 2).

Figure 4-4. Looking at the BCD Information

### ■THE A&R'S BCD DATA

The only method of 'looking' at information in the system is to use an oscilloscope, synchronized to either START (bit 0) or the trailing edge of SYNB (i.e., bit 54), to monitor the BCD line of the A&R. Since the BCD data in the A&R is recirculated once each word-time when the calculator is not busy, that data can be seen on the BCD output. Figure 4-1 shows an example of data on the BCD line when the display is:

-1.234567890 09

*BCD data-transfers with the A&R are controlled by the BDE signal which, in turn, controls a bi-directional amplifier on the Father Board.*

Note that negative exponents are handled by the A&R in the ten's-complement notation.

### ■THE MODEL 5 OPTIONS

When a Model 5 Statistics Keyblock key is pressed, control of the system is transferred to the keyblock ROMs by a 'Select ROM Group B' (SRB) signal from the I/O processor. The keyblock ROM instructions are then serviced by the mainframe data-processing circuits — the C&T, A&R, and I/O processor — in the same way as mainframe ROM instructions are serviced.

When a keyblock key is pressed which requires that either the plotter interface or the data storage circuits be used, control of the system is transferred to the appropriate circuit's ROMs by a Select ROM Group C (SRC) or, for plotter control, a GIOE signal from the I/O processor. These ROMs also use the mainframe data-processing circuits to service the required instructions. Control of the data being input or output by the optional circuits is accomplished by the I/O processor, which is under control of the associated circuit's ROMs.

The processor outputs the signals GIOE and YINTF to enable the plotter interface if the plotter is not busy. The data storage circuits use the BCD line to receive the address of the data being input or output. Then, during a subsequent word time, these circuits input or output the BCD data on the BCD line (see 'The A&R's BCD Data').

The Statistics PROM circuit contains eight-bit keycodes which are input, bit-parallel to the processor on data lines C1 through C8. The processor outputs the keycodes, bit serial, on the EXT line where they are input to, and then processed by, the C&T. The C&T is being controlled by instructions from the keyblock ROMs. Unlike the keyboard keycodes, the PROM keycodes must be 8-bit codes; so the two zeros in the most significant bit positions are not added by the C&T circuit.

## CHAPTER 5 TROUBLESHOOTING ROMS

### INTRODUCTION

The information in this chapter will assist you in repairing Model 5, Model 46, or Model 81 Calculators which contain defective ROMs. The test procedures provided in this chapter must be successfully completed before the repair procedures in Chapter 6 are begun.

#### Recommended Test Equipment

Table 5-1 lists the equipment necessary to test the ROMs in each of the calculators. If the recommended test equipment is not available, any instrument which has specifications equal to, or better than, the recommended equipment may be used.

### THE ROM-TEST SYSTEM

Complete operating and service information for the ROM-Test System is provided in the 'ET 7083 ROM Tester Operating and Service Manual' (09805-90010).

The ROM-Test System consists of an ET 7083 ROM Tester, a 9821A (Opt 001), and the programs and data from the service cassette (see Table 5-2). This system provides a means of testing each ROM in the preprogrammed calculators without removing the ROM from the circuit board.

#### ROM-Test Software

The software (i.e., the data from the service cassette) is used by the 9821A Calculator to control the ROM tests (see Table 5-2). The three files used during each test contain the following information:

- The ROM Test Binary Program performs each test by providing the correct signals to the ET 7083 ROM Tester and interpreting and storing the test results.
- Either the pass/fail or list checksums program may be used. These programs 'call' the binary program and output the test results for the technician's use. The pass/fail program prints only "FAILED IS AND WS" or whichever checksum was incorrect, together with the associated ROM number of those ROMs which fail their test. If all ROMs pass their test, PASS is displayed. The checksum lister program lists the Is and WS checksums, together with the associated ROM number, of all ROMs on the circuit board being tested.
- The third file used during each test contains data which is stored in the 9821A data registers. This data selects the ROM to be tested on the circuit board, so different data must be used to test the various ROM boards.

#### System Operation

When the software is properly loaded, the correct system connections have been made, and RUN PROGRAM is then pressed, the pass/fail or checksum lister program calls the binary program (special program "RT"). This transfers control of the tests to the binary program. The binary program tests the ROMs and records the results of the tests in 9821A data registers. The control program then outputs the results for the operator.

#### The ET 7083 ROM Tester

The ROM Tester interfaces the 9821A to the ROMs being tested and also provides the timing signals required for the ROMs to operate correctly. When Model 5 ROMs are being tested, dc power is provided for the ROMs; dc power for Models 46 and 81 ROMs must be provided either by the device-under-test (DUT) power supplies or from an external source; the ET 7074 power supply box can be used for this purpose.

### ROM TEST PROCEDURE

Before switching the ET 7083 ON or applying power to the ROMs, verify that the ROM-Test System is correctly installed and the appropriate software is loaded into the 9821A. If any doubt exists about the installation procedures, consult the ET 7083 ROM Tester Operating and Service Manual.

#### CAUTION

DAMAGE MAY RESULT IF THE MODEL 46 OR MODEL 81 16-PIN ROM-CLIP IS IMPROPERLY CONNECTED. BEFORE APPLYING POWER TO THE ROMS ALWAYS VERIFY THAT THE PINS ON THE CLIP ARE ALIGNED WITH THOSE ON THE ROM. THEN VERIFY THAT THE PINS ON THE CLIP ARE NOT SHORTED TO THE METALLIC COVERPLATE ON TOP OF THE ROM.

## CHAPTER 5

### TROUBLESHOOTING ROMS

#### NOTE

The Models 46 and 81 Calculators have three jumper wires on the mother board which must be removed before the ROM tests are begun. These jumpers are located under the keyboard and are marked 'WS', 'IA', and 'SYNC'.

When both the DUT and the test system have been properly prepared to perform the ROM tests, the ROM tests can be performed by pressing: END, EXECUTE ... RUN PROGRAM. Depending on the control program (i.e., pass/fail checksum lister) being used, the results of the tests are presented either by the 9821A printing the ROM number FAILED IS and/or WS of those ROMs which fail or by the 9821A printing the ROM number and the associated checksums of all ROMs tested. In most situations, the former presentation, obtained by using the pass/fail program is preferable. If, however, you are using the checksum lister program, then the test results for each ROM must compare exactly with the printouts shown in Table 5-4.

#### Interpreting the Test Results

If all ROM tests result in failure indications, verify that the test system is installed correctly and the correct software is being used. If a Model 46 or a Model 81 is being tested, verify that the jumpers on the mother board are removed. If the test system is properly installed, ensure that the power supply, clock (both  $\Phi 1$  and  $\Phi 2$ ), and sync inputs to the ROMs are within the limits specified in the ROM tester manual. If all of the above checks are satisfactory, verify proper system operation by performing the ROM tests on ROMs which are known to be operating correctly. (Any circuit board which contains ROMs and operates correctly may be used for this purpose.) If the system appears to be operating correctly, or more of the ROMs originally being tested are defective. All ROM tests, except the test on ROM 0, require that at least one other ROM be operating correctly before the tests can be successfully run. Thus, if a ROM, which is used to select the ROM to be tested, is defective, neither ROM can be tested satisfactorily. ROM 0, for example, is used during testing of all other ROMs and, if defective, may cause all ROM tests to result in a failure indication. Table 5-3 shows ROMs which must be operating correctly before the indicated ROM can be tested. Correlating the information in the table with the test results should indicate which ROM (or ROMs) is defective.

ROMs in which the inputs or outputs have become shorted to ground or to one of the power supplies will prevent ROM tests from being properly performed; only 0's or 1's will be output by the ET 7083 as the checksums. Those types of failures must be found by removing ROMs until the shorted ROM is isolated. Then, replace the defective ROM and rerun the ROM tests.

#### CAUTION

ALL MOS CIRCUITS ON THE CIRCUIT BOARD MAY BE DAMAGED IF THE +6V POWER SUPPLY IS SHORTED TO GROUND - EITHER ON THE CIRCUIT BOARD OR INSIDE AN INTEGRATED CIRCUIT. IF THIS TYPE OF FAILURE OCCURS, DO NOT APPLY AC POWER UNTIL THE SHORT HAS BEEN REMOVED.

The ROMs must be satisfactorily tested before the board tests in Chapter 6 are performed.

Table 5-5 shows the functions assigned to each of the ROMs in the preprogrammed calculators.

#### IMPORTANT NOTE

When replacing ROMs, always verify that the new ROM and defective ROM are marked with the same part numbers.

Before returning the calculator to the customer, perform the appropriate calculator test sequence in Chapter 6.

## CHAPTER 6 TROUBLESHOOTING CIRCUIT BOARDS

### INTRODUCTION

The information contained in this chapter will assist you in repairing the preprogrammed calculator circuit boards. All ROMs on the board being tested must have been satisfactorily tested (see Chapter 5).

Before testing any board and after making any required repairs, perform the appropriate key test procedure.

#### Chapter Organization

This chapter is organized into two sections: The first section contains information describing the repair of circuit boards using an ET 7074 Board Tester. The second section provides information for repairing the various circuit boards where an ET 7074 Board Tester is not available. Additional information is provided at the end of the chapter which describes general troubleshooting hints.

#### Recommended Test Equipment

Table 6-1 lists the test equipment required to troubleshoot the circuit boards. If the recommended test equipment is not available, any instrument which meets or exceeds the required specifications may be used.

### REPLACING DEFECTIVE PARTS

#### Damaged Circuit Boards

When one of the MOS/LSI circuits is being replaced, particular care must be taken to avoid damaging the circuit board. If a circuit board is inadvertently damaged by excessive heat, or should a trace or solder pad peel off the circuit board, appropriate repairs (or circuit board replacement) must be accomplished before the unit is returned to the customer.

#### Replacing Display Units

There are six *different* luminous-intensity categories of LED units; the LEDs on each display board are matched at the factory. Therefore, when replacing a LED unit, always ensure that the alpha code on the back of the replacement unit matches the code on the defective unit. Separate part numbers are available for each intensity (see Chapter 7). If a replacement unit of the same intensity is not available, another intensity (i.e., alpha-code) may be used ONLY WHEN AN OBVIOUS MISMATCH DOES NOT RESULT. Before soldering the replacement unit in place, be sure that it is correctly aligned with the existing units.

#### Replacing A&Rs or C&Ts

At the time of this printing, either MOSTEK or AMI manufactured A&R or C&T units may be used as replacement parts for any calculator. If incompatibilities are found, you will receive information describing those incompatibilities via CPD Inter-Office Service Memos (IOSM).

### THE BOARD-TEST SYSTEM

The board test system consists of an ET 7074 Board Tester, a 9821A (Opt. 001) Calculator, a duplicate of the board being tested (i.e., a standard), and the software listed in Table 6-2. Information describing the system installation procedures is provided in the 'ET 7074 Board-Test System Operating and Service Manual'.

#### System Operation

Tests on the circuit boards are performed under control of the 9821A. The test system first attempts to synchronize the device-under-test (DUT) with the standard unit. Then, if the two boards synchronize, the tester utilizes commands from the 9821A to perform identical operations in the DUT and standard unit while, at the same time, comparing the DUT's inputs and outputs to those of the standard unit. If any of the inputs or outputs fail to compare, the test is stopped and information which describes signals in error and when the error occurred is sent to the 9821A. The 9821A then lists the error information, after which the tester is instructed to retest the circuit board. If the DUT fails the retest, the error information is again printed. Otherwise, 'RETEST' is printed. If, at any time, the tester sends the 9821A non-valid error information, 'MALFUNCTION' is printed to inform you that the test-system malfunctioned.

#### The 9821A Software

When properly used, the 9821A software (see Table 6-2) controls the tests being performed by the system and outputs the test results to the operator. The following explanations describe the software used for the tests.

## CHAPTER 6

### TROUBLESHOOTING CIRCUIT BOARDS

36	250	Spare File
37	75	Spare File
38	75	Spare File
39	75	Spare File
40	75	Spare File

The Binary program, special program 'BDT', controls the information input to, and output from, the 9821A. After being 'called' by the control program, the binary program uses the commands in the 9821A data registers to specify operations performed by both the DUT and the standard unit. The test results are received by the binary program and stored in designated 9821A data registers where they can be recalled, then printed, by the control program.

The control program 'calls' special program BDT and, when the test is complete, recalls the test results from appropriate data registers and prints the error messages on the printer. The program then returns control of the tests to the binary program so the board can be retested and the results of the retest printed.

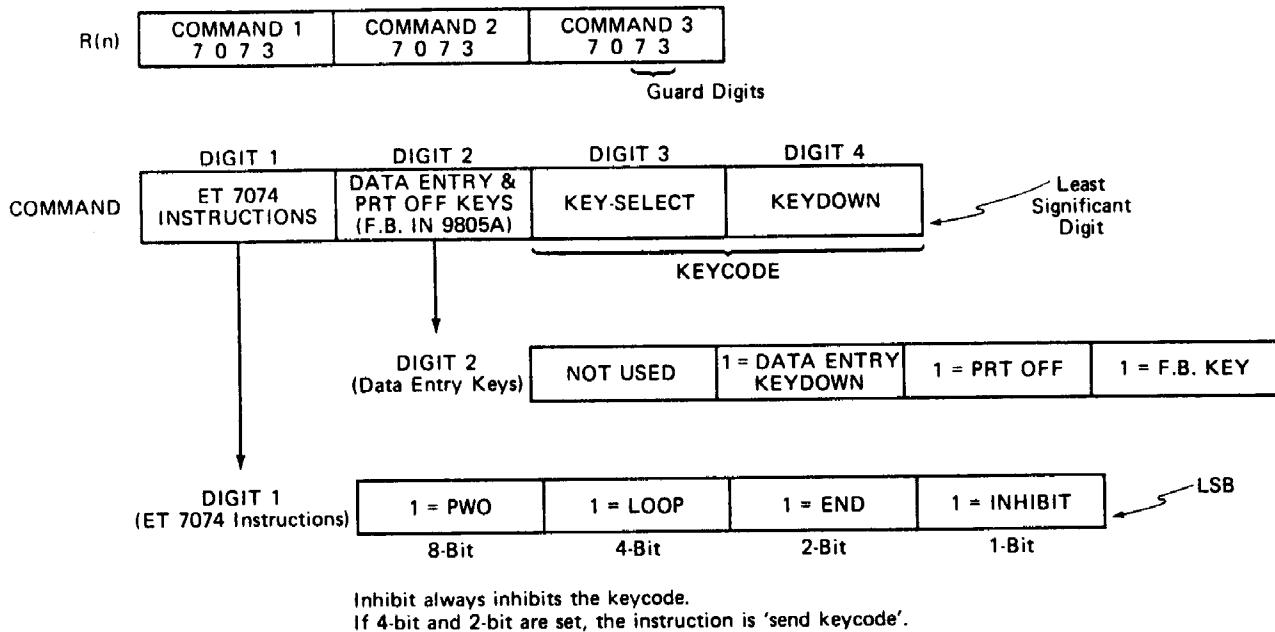

If the binary program receives a non-valid error code from the tester, the control program prints 'MALFUNCTION'.

The commands stored in the 9821A data registers are unique to each type of circuit board. Each command consists of four BCD digits (see Figure 6-1). Because three commands (i.e., 12 BCD digits) are stored in each register, use of the guard-digits is required. Thus, a program is required to list or load the entire 12-digit command-set in each register (Figure 6-2). Each command in the data registers are in three parts:

- The most significant digit (MSD) specifies the function of the command. A BCD 6 is 'send keycode' and an 8 or 9 instructs the tester to issue a PWO signal. A 7 or 1 instructs the tester to 'inhibit the keycode'; the keycode is set but comparisons of the DUT and standard unit signals are not performed. This allows initialization of the board before tests are begun. A BCD 4 instructs the tester to 'loop on the keycode' (use of a BCD 4 is described later in this chapter). A BCD 2 indicates the test is complete.
- The next BCD digit specifies the data-entry format (e.g., AUTO DECIMAL on the Model 5 and Model 81) and PRINT OFF modes of operation. The most-significant-bit (MSB) position of this digit is not currently used and the LSB position is only used to specify that the keycode is for the 9805A Stat Block.
- The final portion of each command is the two least significant digits. These digits specify the keycode which is issued by the command.

## CHAPTER 6

### TROUBLESHOOTING CIRCUIT BOARDS

For Example:

A command 7073 indicates a keycode 73 which is inhibited.  
 A command 6023 indicates a keycode 23 which is sent to boards.  
 A command 6524 indicates a keycode 24 from the function block to be sent with AUTO DECIMAL key down.  
 A command 6226 indicates a keycode 26 sent with PRT OFF down.  
 A command 2000 indicates the end of test.

## CHAPTER 6

### TROUBLESHOOTING CIRCUIT BOARDS

#### ET 7074 TEST PROCEDURE

##### NOTE

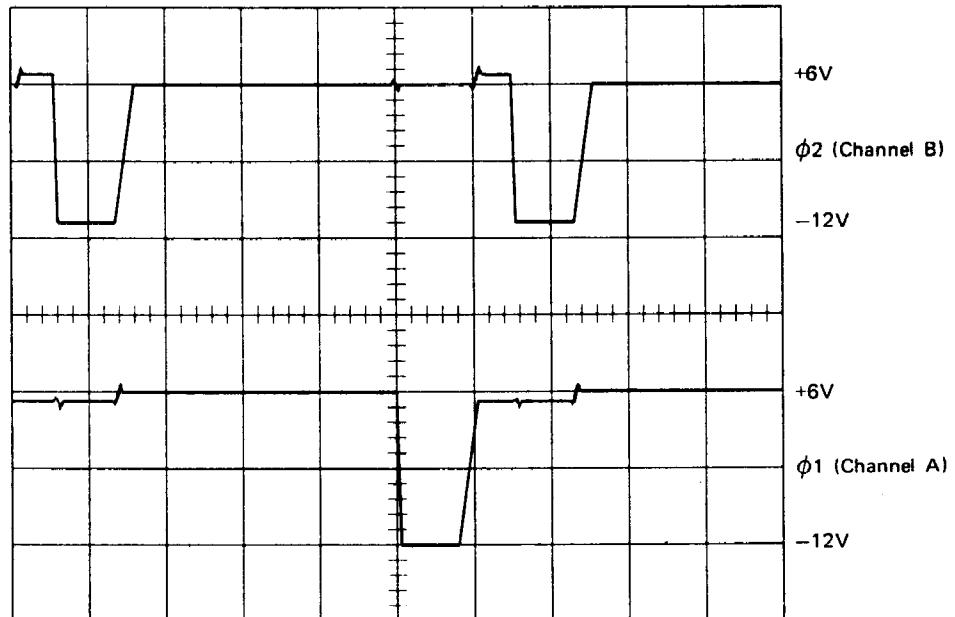

The Board-Test System may not provide understandable test results if either the board being tested or the standard unit contains any defective ROMs.

Before beginning this test procedure, perform the procedure in Chapter 5. Then, verify proper power supply and clo operation. The power supply specifications are given in Table 6-3, while the method of testing the clocks is shown Figure 6-3.

Table 6-3. Power Supply Specifications

NOMINAL VOLTAGE	46/81 LIMITS	9805A LIMITS
+5V (9805A)	N/A	+4.75 to +5.25
+6V	+5.5V to +6.5V	+5.6V to +6.6V
+15V	+14V to +16.5V	+14.1 to +16.2
-12V	-11V to -13V	-11.2 to -13.2*

\* The ET 7074 tests on the 9805A -12V supply are dependent on the +6V supply output.

DISPLAY: ALT B (A&B) + UP	

Figure 6-3. Scope Settings and Waveforms for Clock Tests

## CHAPTER 6 TROUBLESHOOTING CIRCUIT BOARDS

If testing the power supplies and clock inputs to the board indicates any failures, those failures must be corrected before continuing subsequent tests.

Verify that the C&T and A&R circuits in the standard unit are from the same manufacturer (i.e., either MOSTEK or AMI circuits) as the corresponding circuits in the DUT. The two manufacturers build these circuits somewhat differently, resulting in slightly different operation. Thus, if a circuit is tested by comparing it with a similar circuit from a different manufacturer, incorrect test results will occur.

### NOTE

If, after performing tests using the ET 7074, you are not sure what is causing your particular failure, you may wish to perform the test procedures at the end of this chapter.

### IMPORTANT NOTE

The C&T in both the standard unit and the DUT must be from the same manufacturer – either MOSTEK or AMI. This also applies to the A&R in both units.

Now install the board being tested into the test system and load the correct programs into the 9821A. Information describing the installation procedures is provided in the 'Board-Test System Operating and Service Manual'.

After the system is properly installed and the appropriate software is loaded into the 9821A, the board tests may be run by pressing END, EXECUTE...RUN PROGRAM. If you are not sure what software to use, load, then run the program in File 0.

### Interpreting the Test Results

If 'PASS' is displayed by the 9821A, the board is operating correctly. If, on the other hand, 'MALFUNCTION' is printed at any time, the 'test system' is *not* operating correctly. In the latter case, the test should be rerun. If MALFUNCTION is again printed, the test system is defective and must be repaired before further tests can be performed.

It should be noted that the test system's checks of the DUT's circuit boards are so thorough and accurate that failures are sometimes found in calculators that *appear* to be operating correctly.

### NOTE

If the 9821A displays 'NOTE 25', special program 'BDT' is not stored in memory; either the incorrect program was stored in memory or none of the special programs exists in memory.

If the DUT fails the test, the 9821A will first list all information describing when the failure occurred; this information includes the last command and keycode issued and the precise word-and-bit-times during which the first incorrect signal was detected. The important facts in this printout are:

- If the command number is 0, then the DUT never fully synchronized with the standard unit. This may be due to power supply, clock, PWO, or SYNC failures, whichever is indicated in the incorrect signal listing.
- If the failure is in any command other than 0, the failure occurred *after* the two boards were synchronized. The information in this printout is particularly useful in duplicating the failure using the DUT's keyboard. Duplication of the failure is accomplished by using Table 6-5 to find the command (hence, the keycode) which was being processed when the failure occurred. The key(s) corresponding to that keycode should then be pressed to duplicate the failure. If you wish to continually repeat those keycodes, the keycode looping program from File 30 may be used in place of the control program. When 'COMMAND' is displayed, enter any 4-digit (from Table 6-5) command you wish to test. *The last command must be 4000*, which automatically starts the test. More than one command may be entered.

Figure 6-4. The Keycode Looping Program

#### NOTE

This program should be used in place of the control program. Then, when 'COMMAND?' is displayed, enter any 4-digit command from Table 6-5; the last command entered must be 4000.

The next information on the 9821A printout is last addresss, address (i.e., current address), group and ROM. This information indicates which ROM was active, together with the current and preceding address, when the failure occurred. Remember, there are 4 ROMs in a quad-ROM and no more than 2 quad-ROMs or eight single ROMs in a group.

#### NOTE

Ignore the ROM Group information when testing 9805A circuit boards.

Either IS1 or IS2 is printed next. IS1 indicates that the C&T, A&R, and processor are all executing the ROM instructions. IS2 instructions are received only by the I/O processor.

If the last WS signal issued was from the C&T, 'WS FROM C&T' is printed. If the last WS signal originated in a ROM, a printout is given.

If the next printout is 'DSTC' (data storage to C register in the A&R), then a data storage unit, located on the DUT, was inputting BCD data to the A&R when the failure occurred. If DSTC is printed and, later in the signal error printout, a BCD error is printed, the data storage unit is defective.

WORD and BIT, the next information provided, tells you exactly when the error occurred after the last keycode issued. If the bit-time printed is greater than 55, the systems probably were not synchronized.

## CHAPTER 6

### TROUBLESHOOTING CIRCUIT BOARDS

After the word and bit information is printed, a complete list of signals which were incorrect at the time the first error was detected, is provided. The signal which is printed first is usually the first incorrect signal found by the tester. Table 6-4 provides a few of the more common failures and the associated indications from the printout.

When the first test is complete, the board is retested and the error information is again printed (if the retest is accomplished with no failures, 'RETEST' is printed). It is particularly important to note any differences found during the retest. If a considerable number of differences occur, you should rerun the entire test. Then, compare all of the printouts and determine which signals were consistently incorrect. Those signals are probably the key to isolating the hardware failure.

#### The ET 7074 Display

The ET 7074 displays three numbers after detecting an error: The two-digit error number corresponds to the lowest-numbered signal which failed the test (see Tables 6-6). The BIT and WORD display information duplicates the information on the printout.

**Table 6-4. Common Failures and Associated Error Signals**

SIGNAL(S) IN ERROR	POSSIBLE CAUSE
COMMAND 79 Keycode 30 (Model 46)	DUT and standard C&T's dissimilar manufacturer
DSTC with BCD errors	Defective data storage circuit
BCD errors (Models 46 or 81)	Probably defective data storage circuit, but could be A&R or processor
BCD errors (9805A)	Defective A&R or I/O processor
Ia errors	Probably defective C&T
WS errors (Not 'WS from C&T')	Probably defective C&T
Is = 0, with BCD or CRY error	Defective A&R
C1 through C18 errors	Defective I/O processor or associate output circuit
CRY or SRT errors	Often defective A&R
SCE errors	Defective I/O processor
COMMAND 0, WORD 0, SYNC error	Defective C&T
COMMAND 0, WORD 0, clock error	Defective clock driver
COMMAND 0, WORD 0, PWO error	Defective PWO circuit or defective C&T (SYNC)
COMMAND 0, WORD 0, IOC1, 2, or 3 error	Defective C&T
Word 0 errors of the first uninhibited command	Defective C&T
All printer hammers chatter	TP or TR inputs to processor incorrect

## MODEL 46 AND MODEL 81 CHECKOUT PROCEDURES

### Initial Checks

Before an attempt is made to repair the calculator, make the following quick checks to ensure that a failure has actually occurred:

1. Verify the customers complaint and ensure that the complaint is not caused by a user error.
2. If the calculator is completely inoperative, check the line fuse; replace it if necessary. If the line fuse blows again, the primary power circuit or a power supply is shorted and must be repaired before subsequent tests can be run.

### Model 46 Display Checkout

#### NOTE

Model 46 units with serial numbers less than 200 may not display 0.00 when switched on. This symptom may be corrected by pressing **CLEAR**. The repair of this problem is not included under warranty.

The following key sequence will check the Model 46 display for missing segments.

PRESS: **8 . 8 8 8 8 8 8 8 8 8 CMS EEX CMS 8 8**

DISPLAY:

**-8.88888888-88**

#### NOTE

This test does not check all of the decimal-point segments.

### Model 46 Printer Checkout

The following key sequence will check the Model 46 printer operation.

PRESS:

**CLEAR**  
**1 2 3 4 5 6 7 8 9 0 CMS**  
**CHS**  
**e<sup>x</sup>**  
**PRINT**

**PRINT**

CORRECT PRINTOUT:

**CLEAR**  
**-1 2 3 4 5 6 7 8 9 0 + 0 0**  
**zS**  
**e<sup>x</sup>**  
**9.999999999 + 9 9 0**

The keyboard and basic Model 46 operation may be checked by performing the Key Sequence Test (Table 6-8).

## CHAPTER 6

### TROUBLESHOOTING CIRCUIT BOARDS

#### Model 81 Printer and Display Checkout

The following sequence will check the Model 81 display for missing segments and the printer operation. The DECIM/ key must be down.

## CHAPTER 6 TROUBLESHOOTING CIRCUIT BOARDS

### 9805A CHECKOUT PROCEDURES

#### Initial Checks

Before an attempt is made to repair the Model 5, a few quick checks should be made to ensure that a failure has actually occurred:

1. Verify the customer's complaint and ensure that the complaint is not due to some type of user error.
2. Check for an improperly installed system.
3. If the calculator is completely inoperative, check and, if necessary, replace the line fuse. If the line fuse blows again, the instrument is defective and must be repaired.
4. Disconnect any installed peripherals and verify that a peripheral is not the source of the trouble.
5. Use the special System Test PROM (-hp- P/N 9805-90031) to check the calculator — see 'Using the System Test PROM' on the following pages.

#### NOTE

The Power Supply Test Assembly (5060-9199) should be installed in one of the I/O slots (component side to the left) and each of the power supplies tested before performing any of the following procedures. Each power supply output should be within the tolerances given below.

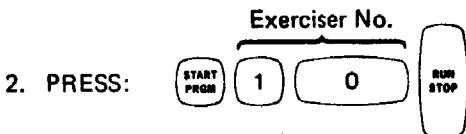

Supply	Tolerance
+5Vdc	+4.75 to +5.25
+6Vdc	+5.6 to +6.6
-12Vdc	-11.2 to -13.2
+15Vdc	+14.1 to +16.2

6. A final test for the 9805A is to test the keyboard keys. This is accomplished by pressing each key, one at a time, and verifying that the correct operation occurs.

#### Using the System Test PROM

The Model 5 'System Test PROM' is programmed to test either the basic calculator, the data storage registers, the printer, or the plotter I/O card (which includes a cursory test of the 9862A Plotter). To use the PROM, perform the following procedure:

1. Switch the calculator OFF, and install the PROM. Then, remove any installed keyblock and peripheral (other than the plotter) and switch the system ON.

Exerciser 10 is selected to test the basic machine. This key sequence can be used for other exercisers by replacing the 10 with the appropriate exerciser number (20, 30, or 40).

2. PRESS:
3. When 3.14 is printed and displayed, exerciser 10 is complete and the resulting printout should be the same as the exerciser 10 listing provided on the following page.
4. If any exerciser fails to run properly, see Table 6-9.
5. Exerciser 20 (Data Storage Register), 30 (Printer), or 40 (Plotter) may be run by performing the instructions given below, then using the key sequence from step 2 (with the appropriate exerciser number) to run the test.

## CHAPTER 6 TROUBLESHOOTING CIRCUIT BOARDS

### NOTE

Exerciser 10 must be successfully completed before continuing to any other exerciser.

CHAPTER 6  
TROUBLESHOOTING CIRCUIT BOARDS

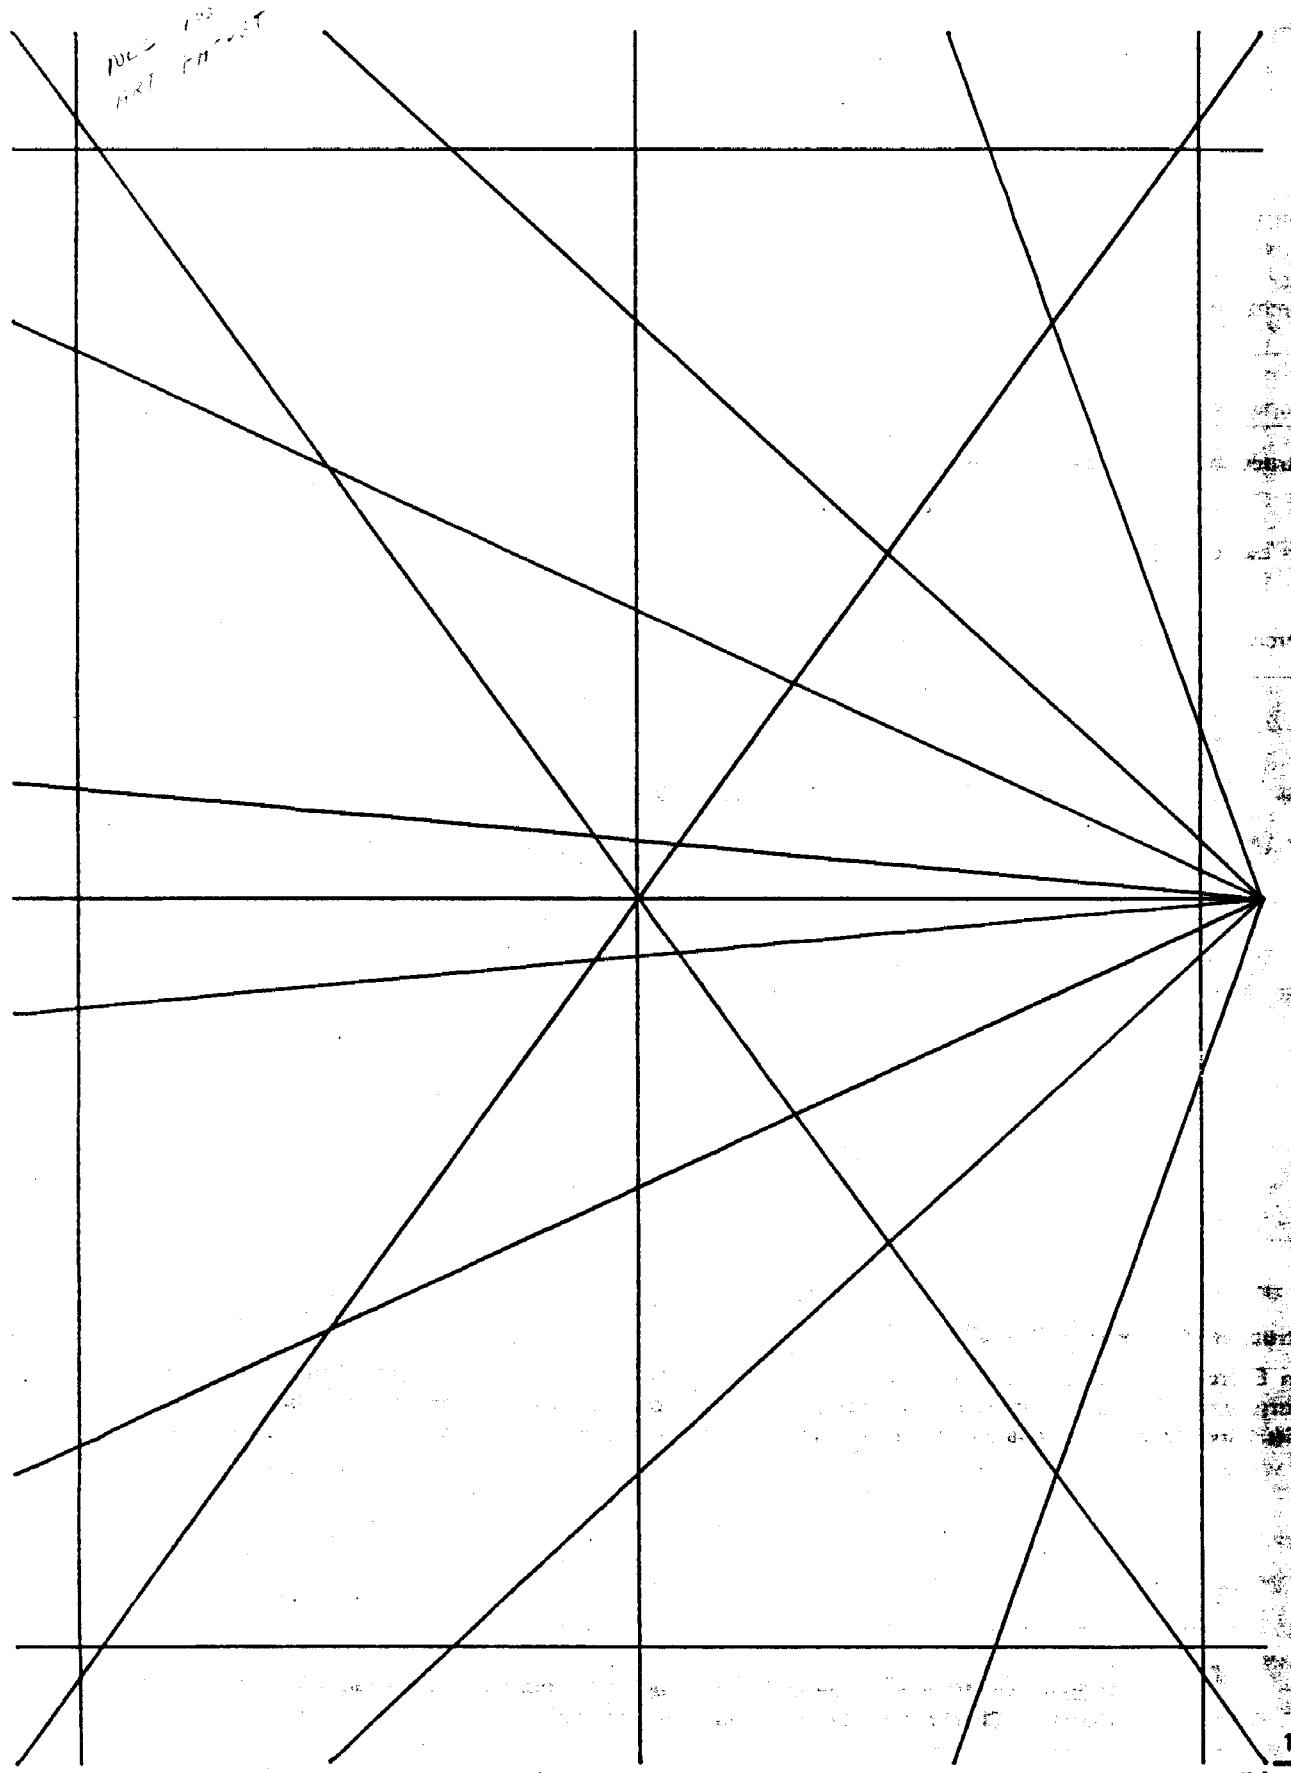

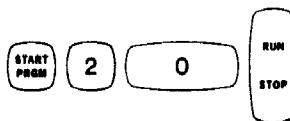

Figure 6-5. Results from Exerciser 40

## CHAPTER 6

# TROUBLESHOOTING CIRCUIT BOARDS

**Instructions for Exerciser No. 20**

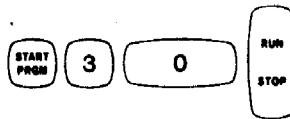

Run Exerciser 10, then PRESS:

After 'DATACLEAR' is printed, input the number of registers which are installed in the calculator (30) and press RL. Each of the nine checks begins with the printing of DATA= 29 (the number of registers minus 1). Each of the 9 tests should result in a printout of the data in each register, separated into groups of 10 (i.e., 3 groups of 10). Each individual check is complete when END is printed. The final (9th) printout is one decimal for each data register. The complete exerciser may take up to 15 minutes.

**Instructions for Exerciser No. 30**

Run Exerciser 10, then PRESS:

Exerciser 30 should result in the following printout.

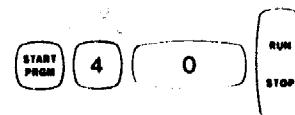

```

    CLEAR
X00000000000B+00S+
Y11111111111C111%X

#888888888888MG8888Z
-999999999999A-99L#

```

**Instructions for Exerciser No. 40**

Run Exerciser 10 before beginning Exerciser 40. The plotter exerciser completely checks the plotter I/O card, but is only a cursory check of the plotter. Before beginning the test, place a sheet of paper on the platen and set the two plot limits 1 inch in from the edges of the paper. Then, run the exerciser by pressing:

**NOTE**

If Exerciser 40 runs properly, but the customer's plotter routines fail, the 'Statistics Keyblock Checkout Procedure' should be performed.

### TROUBLESHOOTING CIRCUIT BOARDS

#### STATISTICS KEYBLOCK CHECKOUT PROCEDURE

##### NOTE

Exerciser 10 of the 'System Test PROM' must be successfully performed before this procedure is begun.

##### NOTE

This procedure should be used when you need to determine if a STAT keyblock is defective and a substitute keyblock is not available. If this procedure can successfully be performed and the customer's STAT Model 5 doesn't operate correctly, the PROM should be suspect. If this procedure cannot be performed correctly, the keyblock should be suspect. DO NOT SKIP STEPS UNLESS INSTRUCTED TO DO SO.

#### Setting Up the 9862A Plotter

Place a sheet of 8½" x 11" paper on the plotter platen and press the PAPER HOLD button down. Then, set the plot graph limits approximately 1" in from each of the paper's edges (see arrows on Figure 6-6). Remove any installed PRC

#### One Variable Checkout Procedure

##### NOTE

Part of the following procedures require plotter operations. If a plotter is not installed, perform only the specified steps. If any doubt exists as to correct plotter operation, perform Exerciser 40 of the 'System Test PROM'.

Remove any installed PROM, then ensure that the plotter (if installed) and calculator are properly connected and switched ON. Then, press the following keys in the exact sequence given and compare the printout (and plot) with the shown. If an error is made during an entry, return to step 1.

### TROUBLESHOOTING CIRCUIT BOARDS

#### DISPLAY AND PRINTER CHECKOUT PROCEDURE

##### NOTE

This procedure only checks the printer and not the printer drive circuits on the mother board. If a printer fails this test, the customer and kit printers should be exchanged to determine if the printer or the mother board is defective.

1. Check printer operation by pressing the following keys — in order — and verifying that the resulting printout is identical to the one shown below:

(The **AUTO** and **PRT OFF** keys must be up.)

\* Printout is red

2. If the resulting printout is identical to the above printout, the printer and printer drive circuits are operating correctly. Otherwise, exchange the printer with the kit printer to isolate the defective assembly (see the above NOTE).
3. While performing the tests described in step 1, verify that the segments in the display are operating correctly.

Table 6-9. System Test PROM Symptoms

SYMPTOM	CHECK	PROBABLE CAUSE	ADDITIONAL INFORMATION
Exerciser 10 fails:	1. Remove all peripherals, I/O cards, and optional data storage. 2. If problem still exists exchange (A40) father or (A41) display board. 3. Exchange the printer. 4. Replace the mother board.	Not in basic machine. A40 or A41 failure. Printer failure. Mother board failure.	Problem may be caused by an optional assembly. Since the printer is used to output the results of the test, the printer may be the source of the problem.
Exerciser 20 fails:	1. Exchange any installed Data Storage Resistors.	Failure on the optional data storage assemblies.	
Exerciser 30 fails:	1. Exchange the Printer. 2. Exchange the (A40) or (A41) board. 3. Replace the mother board.	Printer failure. Mother board failure.	Since Exerciser 10 runs properly, 2 and 3 are not probable failures.
Exerciser 40 fails:	1. Exchange the plotter I/O card. 2. Check I/O cable and plotter.	I/O card failure.	11390A Service Kit may be used with customer I/O cable to check the I/O cable and plotter.

## CHAPTER 6

### TROUBLESHOOTING CIRCUIT BOARDS

#### OSCILLOSCOPE TEST PROCEDURE

##### Preliminary Tests

Before performing the oscilloscope test procedure, verify that the calculator power supplies are within the specifications given below; a 3469B, or its equivalent, should be used to make these measurements.

Power Supply	Specification
+6V	+5.5V to +6.5V
+15V	+14V to +16.5V
-12V	-11V to -13V

If any of the power supplies are not within the specified operating limits, it must be repaired before performing further tests on the calculator.

The next test ensures that the clock circuits are operating correctly. To perform the test:

1. Set the TIM/DIV and VOLTS/DIV vernier controls to the CAL position. Then, calibrate both 10004A (or equivalent) input probes and the 180C display as described in the associated operating manuals.
2. Next, set the controls on the vertical amplifier and time base units as follows (settings which are not specified do not affect the set-up):

A and B input switches:	DC
A and B VOLTS/DIV:	.5
DISPLAY:	A
A and B POLARITY:	+UP
TIME/DIV:	1 $\mu$ sec
SWEEP MODE:	AUTO
trigger source:	INT
SLOPE:	—
trigger coupling:	ACF
MAGNIFIER:	X1

3. With the calculator switched OFF, connect the channel A input to U12 pin 2 ( $\Phi 1$ ). Switch the calculator ON, then adjust the TRIGGER LEVEL control until the scope triggers on the negative-going edge of the  $\Phi 1$  signal. Verify the five divisions (i.e., 5  $\mu$ sec) separate the  $\Phi 1$  pulses. The pulse amplitude must be at least -9V to +9V. Repeat this test on the  $\Phi 2$  signal at U12 pin 3. Correct any clock circuit failures before proceeding with 'Scope Set-up Procedure' (see Figure 6-3).

##### Scope Set-up Procedure

This procedure describes the scope settings necessary to adjust your scope to display one 14-digit word of the calculator.

1. Switch the calculator OFF. Connect the channel B probe to U12 pin 8 (START) and the channel A probe to U12 pin 9 (SYNC) jumper on the mother board. Make the same scope settings as previously described, except set the DISPLAY switch to ALT (B sync) and the TIME/DIV to 20  $\mu$ sec. Switch the calculator ON.
2. Adjust the TRIGGER LEVEL control so the scope triggers at the beginning of the positive-going START signal (bit 0). Adjust the A and B POSITION controls so both signals can be seen.
3. Adjust the HORIZONTAL POSITION control to align the leading edge of the START signal with the left edge of the grid. Next, adjust the TIME/DIV VERNIER control until the leading (position-going) edge of the second START signal is aligned with the right edge of the grid.

##### NOTE

If you align the leading edge of the SYNC signal with the last grid division (1 cm from the right edge), then the display is bits 0 through 50; each minor division is one bit-time.

## CHAPTER 6 TROUBLESHOOTING CIRCUIT BOARDS

### Testing the Calculator

#### NOTE

The preceding tests must have been satisfactorily completed before this procedure is performed.

Figure 6-8 is a troubleshooting tree. To use the tree, switch the calculator in question OFF. Press the DECIMAL switch (Model 81 only) down and ensure that the PRINT OFF key is up. If your calculator does not contain the display option, replace the father board (A4) with a display board (A5). If you are repairing a Option 002 Model 81, replace the father board with an *OPT 001* display board. If a Opt 003 Model 81 is being tested, connect the keyboard cable to the mother board rather than the display board.

Now, switch the calculator ON and note the display and printout. Then proceed with the portion of the troubleshooting tree that most nearly approximates the failure indicated by your calculator. Figure 6-7 shows the 'GROUP I' signals; Table 6-10 explains the 'GROUP II' signals.

When repairs have been completed, perform the key test sequence, for the calculator just repaired, provided earlier in this chapter.

Table 6-10. The GROUP II Signals

Signal	Description for Testing
FLG'	To U13 pin 5; signal is usually +5V — low when the PRINT OFF key is pressed and a printing routine is begun.
FLG	To U13 pin 9; should duplicate the FLG' signal.
CARRY	From U11 pin 6; normally 0V — (approx.) 1 positive pulse each digit when CLEAR is pressed.
IOC1	From U13 pin 20; normally 0V — goes high when nearly any key is pressed.
IOC2	From U13 pin 19; normally 0V - goes high at turn-on.
IOC3	From U13 pin 18; normally +6V — goes low when most keys are pressed.
SCE	From U13 pin 17; normally 0V — goes high when most keys are pressed.
EIS1	From U13 pin 15; normally +6V — goes low when most keys are pressed.
EXT	From U13 pin 3; normally +6V — negative pulse for 1 bit-time when a key is pressed.
PWO	To U13 pin 10 (and other MOS circuits); PWO is always +6V except for 500 msec after the ON/OFF switch is pressed.

## CHAPTER 6

### TROUBLESHOOTING CIRCUIT BOARDS

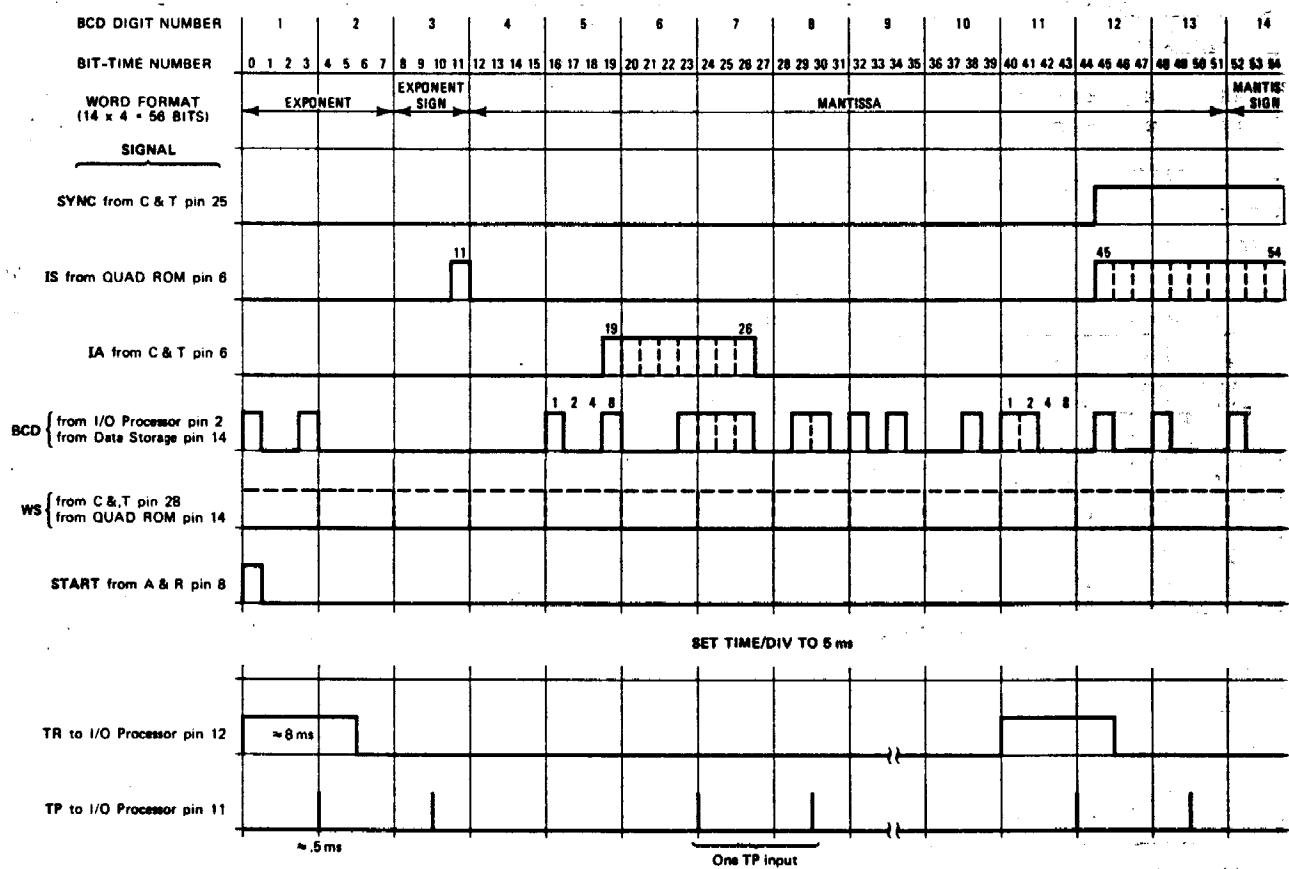

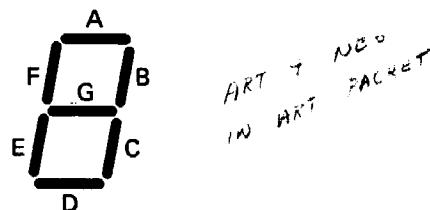

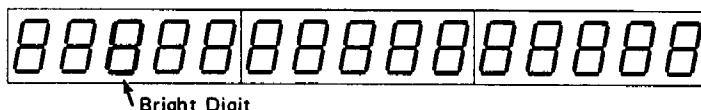

Figure 6-7. The Group I Signals

DISPLAY PROBLEMS

Make up of segment.

1. Bright digits on display.  
a. Anode driver

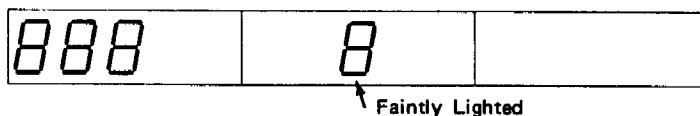

2. Digit has a tendency to turn on next digit. A ghost image appears.

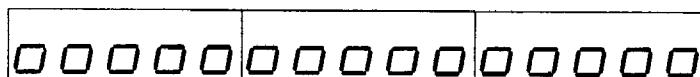

NOTE

If 'G' segment is faintly lighted, it is often caused by the A&R. To correct this problem, change the A&R.

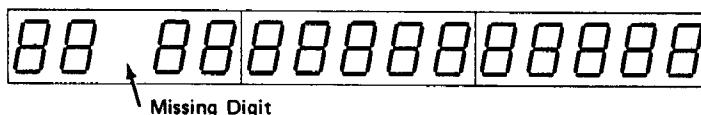

3. Digits missing segments of numbers.  
a. Cathode driver

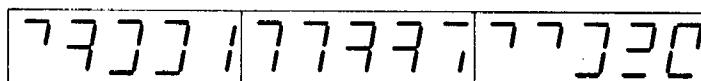

4. All digits missing same segments.  
a. Inductor shorted  
b. Anode driver

5. Single digit missing out of display.  
a. Cathode driver  
b. LED

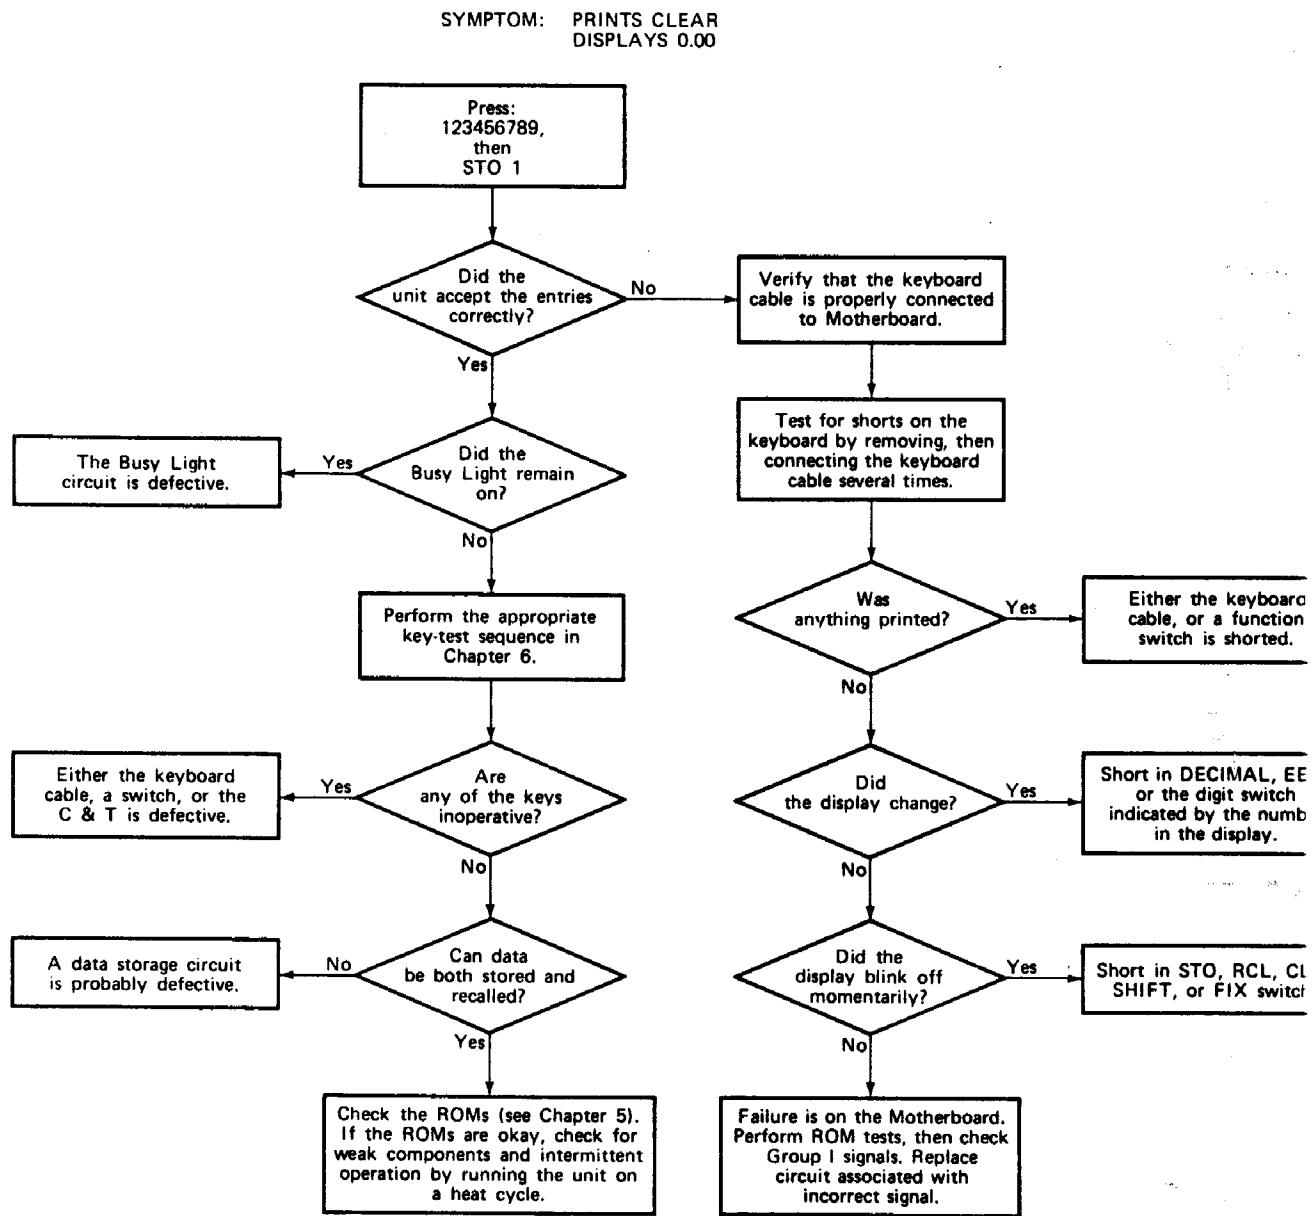

6. Shorted segment of digit.  
a. LED  
b. Anode driver

#### SCHEMATIC NOTES

##### REFERENCE DESIGNATIONS

PARTIAL REFERENCE DESIGNATIONS ARE SHOWN: PREFIX WITH ASSEMBLY OR SUBASSEMBLY DESIGNATION(S) OR BOTH FOR COMPLETE DESIGNATION.

ASSEMBLY	SUBASSEMBLY	COMPONENT	COMPLETE DESIGNATION
A2	NONE	Q1	A2Q1
A2	A1	R1	A2A1R1
NONE	NONE	J1	J1

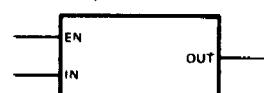

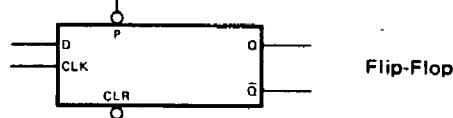

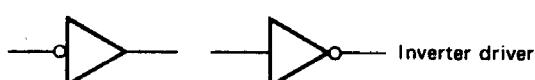

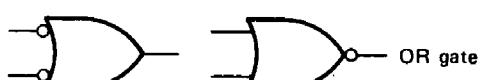

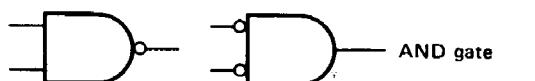

STD-A-506

1. COMPONENT VALUES ARE SHOWN AS FOLLOWS UNLESS OTHERWISE NOTED.

RESISTANCE IN OHMS, CAPACITANCE IN MICROFARADS, INDUCTANCE IN MICROHENRIES

2. GROUNDS: CIRCUIT CHASSIS EARTH
3. DENOTES ASSEMBLY
4. LOGIC SYMBOLS:

Small circle means "low-true" at this input or output.

Input information is transferred to the outputs on the positive edge of the clock pulse. Low inputs to PRESET forces Q high, whereas low inputs to CLR forces Q low; both inputs are independent of CLOCK.

CMOS LATCH (Models 46 & 81): +6V on EN enables the output to follow the input; 0V on EN forces out low.

## CHAPTER 7 REPLACEMENT PARTS

### INTRODUCTION

This chapter provides the information necessary for you to order replacement parts from either Customer Service Center (CSC) or Part Center Europe (PCE), whichever is more appropriate. Separate replacement parts lists are provided for each calculator.

### SPECIAL ORDERING INFORMATION

#### Display Units

Replacement display units should be ordered using the part number for the particular intensity you require (3 ea.). An alpha code is provided on the back of each display unit which specifies the luminous-intensity of that unit; alpha code F specifies the lowest available luminous intensity, whereas code K is for the highest intensity. The replacement parts lists each contain the part number for each intensity.

#### C&T, A&R, and Clock Driver Units

The part numbers for the most recent designs of the C&T, A&R, and clock driver ICs is provided in the parts lists. Please replace defective units with replacement parts obtained by using the part numbers provided in this manual.

#### Printers

The printer in each model calculator (e.g., Model 46 or Model 81) is unique to that calculator. Do not replace the printer from one calculator with the printer from a different model calculator. The printer is a Blue Strip Exchange item.
